Dr. J. P. Peck, of Omaha, died recently, in the 60th year of his age. Dr. Peck was the oldest practicing physician in the city of Omaha, and a man well known and universally esteemed. His health had not been of the best for some time, but he attended to his daily duties until near the end. At that time an affection of the heart developed, accompanied by sinking spells, and the symptoms gradually developed until they proved fatal.

James Porter Peck was born in Summit County, Ohio, October 11, 1821. In the spring of 1850 he graduated at the Cleveland Medical College, and in June was married to Miss Elizabeth H. Quies. He located in Akron, and remained there until 1856, when with his wife and two sons he removed to Omaha.

Dr, Peck was one of the landmarks of Omaha, where he had lived for the last thirty years. He was a man of the strictest integrity and one of the purest of men. His professional brethren esteemed him highly, and those of the people who knew him placed the utmost confidence in him.

Pallas Syringe."

[From the *London Medical Record.*]
"It is a useful Instrument, and will be a formidable rival to the ordinary vaginal douche.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1054-1556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant. Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

CLINICAL LECTURE.

BY DANIEL LONGAKER, M. D.

Lecturer on Obstetrics at Phila. Lying-in Charity, etc.

Reported by T. H. Huzza.

Gentlemen: You will remember an interesting case of cancer of the *cervix uteri* upon which I operated two weeks ago, at which time the specimens were shown you by my colleague. You will remember I removed a large mass of diseased tissue, including most of the cervix up to the internal os, and also part of the posterior vaginal wall which the disease had invaded. The discharge was very offensive, and the mass removed was marked by a stench which makes the disease so horrible. After excising the diseased mass with curved scissors, the surfaces were thoroughtly scraped to bring away as much of the affected tissues as was possible. There was left a large crater-shaped opening or cavity, which was carefully packed with cotton saturated with a 100 per cent. solution of chloride of zinc. The means and methods employed in packing the uterus were those suggested by Van de Warker, in the *Am. Jour. of Obstet.*, March, 1884. The nurse, with rubber stalls to protect her fingers, dipped balls of cotton the size of a hickorynut in the zinc solution and wrung them out. These balls were then carefully packed in with ordinary dressing forceps. There is danger here of causing fistula, as the recto-vaginal septum is very thin and the strong corrosive may penetrate the walls. When this is feared, you should reduce the zinc solution to the strength of 50 per cent., which is sufficiently strong, and yet avoids danger of a troublesome fistula. In this case I used for the first forty hours rolls of cotton saturated with Monsel's solution, and well packed into the cavity. This prepares the parts for the zinc, and renders its action far more efficient. At the end of the time stated the cotton was carefully removed, any clots or shreds of tissue carefully cleaned out of the cavity, and I packed in the cotton saturated with the chloride of zinc, the 100 per cent. solution being used for the upper part, including the apex of the incision and the cavity of the uterus, while the 50 per cent. solution was used for the raw surface on the posterior vaginal wall. In eight or ten days, according to Van de Warker, the slough comes away without much trouble. This period was just two weeks in the present case.

We find, in this dreaded affection, three zones or areas of infected tissue. First is the site of the active disease. Around this is a zone in which are young cells, actively proliferating. The third zone is the part in which the process is just beginning. With chloride of zinc, all these parts may be sloughed out, and the third zone thoroughly removed, as could not be done by other means. You may slough away almost the whole uterus and its glands, which are especially dangerous points. There is no danger of septicæmia as chloride of zinc is a powerful antiseptic. There is no smell, a feature particularly marked in this case. When you remove the slough, be very careful not to pull on it, as there is danger of hemorrhage. Let it come away by its own weight, almost, using just enough force to

guide it. I tried the mass day before yesterday, but it would not come out easily, so I let it alone till this morning, when it was removed without difficulty. The mass of slough shows well the shape and size of the crater-like cavity, which was packed. Above we have the small connected mass corresponding to the size of the uterine cavity, as shown by measurement before packing.

This, gentlemen, illustrates an operation which has greatly ameliorated the condition of the patient, and, let us hope, has entirely eradicated the disease.

I have also to present a case in which you will be doubly interested, as illustrating the mechanism of labor in contracted pelves, and the subject of pelvimetry. The latter is neglected by obstetric teachers, or, if taught at all, is so treated that students gain little that is of practical use to them, and do not obtain ideas that will assist them in the diagnosis and management of such cases. The pelvimeter most commonly used is the instrument of Baudelocque. It is rather delicate and inconvenient. I prefer Matthews', as it is portable, efficient, and, I think, the best obtainable. It can be used, also, to examine the diameters at the outlet, as well as for ordinary external measurements. The scale extends from twenty inches one way to eight inches the other. The pelvimeter is used chiefly to measure externally, the internal means of measuring being with the finger.

This patient whom I bring before you has a height of only fifty inches. She presents distinct evidences of rachitis. You notice here the short forearm, the extremities of the bones being enlarged and thickened. The legs are bent, and the upper portions of the tibiæ decidedly thickened. As a rule, you do not have in rickets the stature so much diminished. You will have a history of late dentition, the lower incisors often not being cut till the second year. The fontanelles will remain open a long time. You will usually find it was a cross, bottle-fed, dyspeptic infant. If you see the mother, she will probably tell you the child did not sleep well, would throw off its cover at night, and perspired profusely.

The pelvis, however, is very marked in its changes, and if carefully observed can hardly be mistaken. Now you will ask me what measurements are to be taken in order to distinguish it from the normal pelvis. First we take the distance between the anterior superior spines of the ilea, which should be about 10¼ inches. Next we find the measurement between the iliac crests, which is 11½ inches. Bear in mind this relationship, for upon it depends the character of the case you may wish to determine. If this relation or ratio is found, you know it is not rachitic. The third measure is the external conjugate, or diameter of Baudelocque. This should be about 8 inches. These are the only measurements that are of any practical importance, and the only ones that need be taken. To attain them the patient should be placed on a hard surface, preferably on a table. A spring-bed is the worst thing possible, as the hips sink in and you cannot reach the spines or crests. Now, letting our patient lie on her back, I will take the first measurement, which is the distance between the anterior superior spines of the ilia. It is here 9½ inches. Now for the distance between the crests. In the normal pelvis we find the crests easily, but here they are not distinct. Instead of spreading out as you go back from the spines, we find the crests go back here almost in a straight line. This feature is to be carefully noted. As we cannot find the widest points, we have a rule in such pelves, *i. e.*, measure two inches posterior to point where anterior spines were measured. We find the second measurement here to be 9¾ inches. At once we would say this was rickets, as we find the normal relation disturbed. In marked cases the distances between crests may be less than that between the spines. Here we find the distance between the anterior-superior spines is very little less than normal, but we find the ratio changed. This is the important point. Now we turn the patient on her side, and take the third measurement. Searching for the fossa below the spine of the last lumbar vertebra, and placing one arm of the pelvimeter on this point, the other arm upon the anterior superior margin of the pubic symphysis, we here find the external conjugate to be 6¼ inches. The early investigators of this subject thought it would be easy by subtracting so much from this to obtain the internal or true conjugate. Not so; the value of it is chiefly in the inference you can draw, and the after examination it leads you to make.

I need not further illustrate on this patient the method of internal measurement, but will explain the principles on this Budin manikin. We have here a movable sacrum, which I will screw up so as to make the true conjugate three inches. Now, take your right hand, with the index and middle fingers extended, the others folded back in the palm, and the patient being on her back with thighs well flexed, introduce it into the

vagina and press well up till you feel the promontory of the sacrum. Marking the position of the subpubic ligament with the forefinger of the left hand, withdraw your fingers and measure the distance you have. It is, you see, three and three-fourths inches. Bnt this is the oblique conjugate which we know bears a fixed relation to the true conjugate. In the normal pelvis the latter is about three-fourths of an inch less than the oblique. We measure the true conjugate on the manikin and find it is three inches exactly. This relation varies in contracted pelves. The inclination and depth of the pubic symphysis may change it. So may the height of the sacral promontory. In rachitic pelves we must subtract a little more than three-fourths of an inch to obtain the true conjugate. In the Mütter Museum at the College of Physicians I examined very carefully the specimens of contracted pelves which are there, and in every one I found it was necessary to subtract one inch from the oblique to obtain the true conjugate.

We found the distance between the spines was nine and one-half inches. This shows that the transverse diameter of the pelvis is about normal. This is to be carefully noted, for if we have plenty of room in the transverse diameter it enables us to deliver where otherwise it would be impossible. The normal true conjugate is four inches, but not till the pelvis is narrowed below three and one-half inches in this measurement is it to be considered a contracted pelvis. Yet a woman of this measurement may pass through labor, and I feel certain that they do very commonly, yet the diminished diameter is not observed. But there is a great difference between the mechanism in a normal case and in *flattened rachitic pelvis*, as this is. The head comes down in the transverse diameter. It is not flexed, as is ordinarily the case, but is semi-extended. The anterior fontanelle is usually in reach, and it is perfectly proper that it should be so. We do not want the head flexed in these cases, as the bi-parietal diameter must pass to one side with one parietal boss, the anterior on a lower plane than the posterior, the so-called Naegele obliquity. It is possible where the pelvis is three and one-half inches in the true conjugate for a woman to give birth to a child unassisted. I have seen a woman give birth to a child by means of the forceps I show you here, my modification of Tarnier's traction forceps, and yet the true conjugate was less than three inches, and the child weighed eight pounds. This woman has been delivered twice; each time the child was dead. It is, therefore, not only justifiable, but it is our duty to induce labor prematurely. In this way we give the child a better chance, and also greatly diminish the risks to the mother. The true conjugate in this case has been shown by repeated examinations to be three inches. We shall induce labor, as near as possible at the thirty-fourth week. The result you shall know in due time. I had intended to review the means to be used and the many points connected with the subject, but as my time will not allow it, I shall postpone these until our next meeting.

COMMUNICATIONS.

SOME RECENT STUDIES AND OBSERVATIONS ON TINNITUS AURIUM.

BY LAURENCE TURNBULL, M. D., PH. G.,

Aural Surgeon Jefferson Medical College Hospital, Phila.

(*Continued from page* 360.)

Tinnitus from Stomach and Liver Disturbance.—We have already referred to disturbance of the stomach in which vomiting may cause tinnitus, more especially in woman during pregnancy. In a recent paper by Dr. E. Méniére (*Revue Mensuelle de Laryngologie, d'Otologie,* etc., June, 1886), he claims that tinnitus may be produced without deafness, due to disease of the stomach alone. In most of our cases there has been more or less impairment of hearing with catarrhal disease of the mucous membrane of the middle ear, causing vascularity and reflex action of the trophic and vaso-motor nerves extending from the stomach to the auditory nerve. Some cases may be accounted for on the theory that the tinnitus is due to the swelling and reflex action in the post-nasal spaces, middle ear, and orifice of the eustachian tubes, by extra secretion of mucus, desquamative epithelium, etc. The air being excluded from the middle ear the stapes is driven inwards, increasing the tension upon the labyrinth fluids. Dr. Méniére refers to the theory of Woakes in support of his conclusions that stomach tinnitus in such cases is due to an affection of the internal ear, which is chiefly supplied by the vertebral artery and a branch of the pneumogastric nerve, and any disturbance is reflected to the latter, the calibre being increased, causing passive congestion of the labyrinth.

The following are two cases of this form of tinnitus, reported by my assistant, Dr. Jones, Aural Clinic, Jefferson:

Case 1. John B. E., age 47. H. D. normal. No discharge. Tinnitus (roaring), two weeks' duration; left ear. Treatment: Hydrarg. chlor. mite gr. ½ every half hour for six hours, followed by Seidlitz powder. Full recovery in three days.

Case 2. J. O'Neil, age 44. H. D. normal. M. T. normal. No discharge. Tinnitus roaring. Two weeks' duration. Right ear. Due to alcohol. Treatment: Hydrarg. chlor. mite gr. ½ every half hour for six hours, followed by a saline.

Both these cases were caused by a prolonged debauch.

Treatment.—Static electricity has also been found of benefit, and we can confirm this statement (see method of using in Manual of Diseases of the Ear, new ed., 1887, p. 537). Bromide of potassium in large doses; but great care must be given to the stomachic digestion by the selection of proper food, use of pepsin, etc.

Gouty or Rheumatic Inflammation of the Ear followed by Deafness, by Peculiar Dry, Rubbing, Tinnitus Aurium.—Case 1. While in London we were called in consultation with Dr. Shilletoe, to see a gentleman who had been for several years a sufferer from severe attacks of gout, with deposits of salts of phosphate of lime in various parts of his body. He had become gradually deaf, and desired his physician to call in a specialist to see what could be done for his relief. We examined his ears, and found a deposit of the lime salts in the membrana tympani in points. There was but little pain, and peculiar dry, rubbing tinnitus aurium.

The treatment we recommended was the free use of the iodide of potassium in ten-grain doses three times a day, in water, while a weak warm solution of the same was dropped carefully into the ear, to act upon the layer of the membrane. The Politzer's air-douche was also employed to free the eustachian tube from mucus. After a treatment of several weeks we were pleased to be informed that the deafness had disappeared, much to the comfort of the patient.

Rheumatic Otitis.—Case 2. June 11, 1885. Mrs. A. P. C., æt. 41. Has suffered from hereditary deafness for years, increasing within the last four years. Five members of her family are very deaf. She resides in a malarious and damp region in the vicinity of a river. She has suffered at times with a dull headache and slight but never decided chill, which could be termed a true shaking ague. Has had several severe attacks of rheumatism, and during the attack she lost her hearing and for a time was completely deaf. After the free use of bicarbonate of potassium, the pain left her, and she was also relieved of her temporary deafness. These attacks have left her with more or less pain at times in the nape of the neck. Membrana tympani opaque, sunken, and a deposit of lymph, etc. She has also the same form of tinnitus. The tuning-fork is heard best in contact with the mastoid, showing some involvement of the labyrinth, etc. What is to be done with this class of cases? Restore as far as possible the parts involved by local and general measures, but above all change in climate for the patient, for we have found that a change from the vicinity of Chester say to New Mexico, or some such change, improves the hearing, while a return to the old locality again brought a return of the deafness. Again, a removing from Pennsylvania to St. Paul, Minnesota, modified and improved the chronic middle ear catarrh.

Tinnitus Aurium of Cerebro-Spinal Meningitis and Diseases of the Teeth.—In the early course of cerebro-spinal meningitis, there is an almost constant complaint of roaring and ringing in the ears, followed by earache, hallucinations of hearing, and soon after by deafness. Ringing in the ear (tinnitus) is commonly enough caused by a diseased condition of the dental organs; and where no immediate cause is found to explain the condition, the teeth are to come in for a full share of attention. As constitutional conditions, predisposing to or exciting the condition, may be enumerated anæmia, continual constipation, disease of the stomach and liver, and various diseases of the brain. Many cases of tinnitus that have long baffled the ordinary attempts at cure have disappeared almost immediately on the extraction of a diseased tooth never thought of in this connection.

Patulous Condition of Eustachian Tube.—In this class of cases, which are generally the result of a relaxed condition of the orifice of the Eustachian tube, the remedy should be the application of a strong solution of nitrate of silver or sulphate of copper or carbolic acid and glycerine to the mouth or faucial orifice of the tube, and subsequently washing it, by the use of the double Eustachian catheter, with the internal use of strychnia, to stimulate the muscle to contract and close the orifice.

The "Aspergillus."—This is often a cause of tinnitus aurium. It is a vegetable parasites or fungus, and is to be removed by the injection of absolute alcohol, or a warm so-

lution of sulphite of sodium. This mould is best seen by the use of the microscope, and can be cultivated on an apple or lemon. The discharge of serous fluid is to be checked by the use of an injection of a strong solution of sulpho-carbolate of zinc or nitrate of silver. A number of these cases of a mild character we have treated after the summer season in patients who have allowed the sea-water to pass into the ears and dampen the hair, or in those who work in damp earth. In these cases a mild solution of an astringent, acetate or sulphate of lead or sulphate of zinc, will remove all the symptoms of itching, deafness, and distressing tinnitus in a very short time.

On the Use of Cocaine and Brucine in Tinnitus Aurium and Painful Affections of the Ears.—Our personal experience with hydrochlorate of cocaine has been quite extensive, and we consider it a valuable remedy in certain forms of tinnitus aurium. It facilitates catheterization of the eustachian tube, when closed by spasmodic action, or when filled with mucus, serum, etc., by the applying of a two or four per cent. solution to the lower nasal passages and the pharyngeal orifice of the tube. Injections of solution of cocaine alone, or followed soon by atropine, morphine, etc., will, by their contracting and sedative action on the blood-vessels, dilate the calibre of the canal, facilitate inflation of the middle ear, and permit injections, gases or liquids to pass into the tube and the tympanic cavity. The buccal and pharyngeal mucous membranes are readily and rapidly anæsthetized by cocaine. All operations on the mucous membrane of the middle ear, pharynx, epiglottis, and larynx, generally considered so painful, are rendered almost painless by its local application, if the drug is pure. Instillations of cocaine into the external auditory meatus in cases of neuralgic earache have been found useful by many reliable observers. So, also, on the acute earaches in children, *i. e.*, Kinnicutt, Thomas, Reder, Landesberg, and many others.

We have performed perforation of the membrana tympani in three cases with entire absence of pain under the influence of cocaine.

The application of painful remedies in acute and chronic purulent otitis, as, for instance, nitrate of silver, sulphate of zinc and copper, chromic acid, alcohol, ether, can be done after cocainization with almost entire relief of pain. Also operations on the walls of the auditory canal, caustic applications to the auricle, and tumors, can be removed with but little pain by subcutaneous injections of cocaine.*

Kirchner (*Deutsche Med. Woch.*, No. 4, 1885,) finds that with twenty per cent. solution of cocaine he is able to produce anæsthesia in operations on the membrana tympani.

Tufal (*Präger Med. Woch.*, No. 7, 1885,) has obtained similar good results. (This is on the healthy membrane, not the inflamed and elevated one ready to break.)

We have instilled a few drops of a four per cent. solution of cocaine into the ear in tinnitus aurium consequent upon chronic otitis media, with the result of lessening both the tinnitus and deafness.

M. George Viau has solved the problem of local anæsthesia in minor surgery and dentistry. After numerous trials of solutions of different strengths, he has found that the soft parts about the maxillæ may be rendered completely insensible by the use of cocaine associated with a two per cent. solution of pure carbolic acid. Five minutes before operation, M. Viau dissolves five centigrammes (one grain) of hydrochlorate of cocaine in fifty centigrammes (ten drops) of the solution, and injects it into the gums, half-way between the neck and the extremity of the root of the tooth. Half of the solution is injected on the palatine and the remainder on the labial side, pressure being made by the finger, when the needle is withdrawn, to prevent the exit of the fluid. Anæsthesia is perfect in three minutes. The quantity of cocaine advised by M. Viau seems somewhat large, but it has been so used in eighty-seven cases without causing any unpleasant symptoms.

We have made several experiments with this combination (crystallized carbolic acid and cocaine), and can confirm the results obtained by Professor Viau.† The pure carbolic or phenic acid of the French should be Calvart's pure, crystallized and dissolved in distilled water.

Brucine, its Local Use as an Anæsthetic in Diseases of the Ear.—We have received from the author ‡ a valuable reprint of some interesting experiments on the use of cocaine and brucine as anæsthetics on the skin and mucous membranes. He states, however, that the latter is not as prompt as the cocaine in

* Turnbull, L. Hydrochlorate of cocaine in acute otitis causes deafness from coryza (Author's Work on Cocaine, Philadelphia, 1885, MEDICAL AND SURGICAL REPORTER, rep., Philadelphia, April, 1885, Manual of Diseases of the Ear, second edition, 1887.

† De l' Anesthesie Locale (pamphlet, p. 23), Officer d' Academie, Professor of School and Hospital Dentaires de Paris.

‡ Dr. Thomas I. Mays, Philadelphia, Therapeutic Gazette, June, 1885.

the same strength. It is, however, on the cutaneous surface where its action is most decided and definite. This is best demonstrated by applying (in solutions of 5 to 20 per cent.) to the hairy parts of the hands and arms, and allowing it to remain for ten or fifteen minutes, and then comparing the sensibility of the skin thus treated with a neighboring point by pulling out the hair." As brucine is always contaminated by strychnine, we have felt unwilling to use an inferior anæsthetic for fear of poisoning the patient. We received a specimen free from strychnine from Dr. May, and employed it in a number of experiments, and the following is an abstract of them in diseases of the ear. To make the solution soluble, it requires five drops of hydrochloric acid to the gramme, which would prevent its use in eye surgery, etc.

With a five per cent. solution of brucine we find that, although it may be more lasting in its effects than cocaine, it is not so sure to produce them, and we think not so readily absorbed. We found it of no service when applied to the skin, but will relieve the pain of irritant applications to mucous surfaces, and generally give relief in cases of furuncles of the external auditory canal and suppurative otitis media. In a few instances, after liberal applications to the nasal cavities, the patient felt uncomfortable for some hours, evidently from the strychnine-like effects of the drug.

Labyrinthine Tinnitus Aurium.—If this be severe and persistent, leeches in front of the ear are to be recommended. Large doses of bromide of potassium and ammonia, tincture gelsemium, hydrastin, and valerianate of zinc have also been found useful by Dr. Field in tinnitus in general.

This most distressing and persistent form of tinnitus, which depends upon disease of the labyrinth, may be, as we have shown, in many instances, from reflex irritation, which must be cured by the removal of the cause. There are many cases in which the noises are from an acute or chronic inflammation of the labyrinth proper, and there are but few agents which cause much impression upon this portion of the nervous system of the ear. The remedy which has yielded the best results is pilocarpine, the active principle of jaborandi.*

Hydrobromic Acid has been claimed by Dr. Woakes as a "specific remedy for congestive labyrinthine conditions, provided always that the auditory apparatus be free from any well marked process which by its presence might tend to keep up increased vascular action." This agent was first employed by Wade,* who claimed that the acid "possesses all the valuable properties of potassium bromide, but lacks its influence on the heart and muscular system;" but this is a mistake, as it was proven by the careful experiments of Professor Edward T. Reichert, of the University of Pennsylvania,† *i. e.*, that it certainly does affect the heart the same as potassium bromide, and as he has conclusively proven, it depresses the muscles, and ultimately paralyzes the heart.

I give a summary of the conclusions drawn from the results of present research, placed for convenient reference in a parallel column, with the conclusions arrived at by the different investigators on the action of the "potassium bromide," representing the physiological action of the alkaline salts.

HYDROBROMIC ACID.	POTASSIUM BROMIDE.
The Circulation: Arterial Pressure.—The arterial pressure is unaffected by very small doses, or a slight rise occurs: moderate doses cause an increase from the first, or a diminution of pressure, followed by a return to or above the normal; large doses cause the pressure to fall, and if sufficient, cause it to fall to zero.	*Arterial Pressure.*—Administered hypodermically it causes diminished arterial tension, with increased pulse frequency. Large doses paralyze the heart, and thus reduce arterial pressure (I. G. Schonten, Archiv der Heilkunde. xii., 2. 1871; Schmidt's Jahr., Bd. c. liv.)
The fall of pressure is due to a depression of the heart muscle.	(See above.)
The rise of pressure to a constriction of the vaso-motor peripheries.	Vaso-motor peripheries irritated, causing constriction (Lewisky, Virchow's Archiv. Bd. xiv., p. 191; Amory, The Phys. and Ther. Action of Bromide of Potassium, Boston, 1872; Meuriot, L'étude de la Belladone, p. 49; Saisson, Schmidt's Jahr., Bd. cxliii.) This action on the capillaries has been denied.
Pulse. — The pulse-rate is not appreciably affected by very small doses; moderate doses sometimes caused a momentary slowing by inhibiting the heart, the pulse then recovering to a variable extent, and being followed by a gradual fall; or, a momentary rise occurs accompanied by a diminution of arterial pressure. this being followed by a diminution to below the normal; or, after large and repeated doses the pulse falls below normal and then becomes exceedingly rapid, or becomes rapid from the first; or may be depressed from the first. All these effects being due to a direct cardiac action, with the above single exception. The increased pulse-rate being attended with a diminution of pressure and small pulse-curves.	*Pulse.* — After slow intravenous injection of a two per cent. solution of the potassium bromide, the pulsations become slower and feebler, the blood pressure falls, and the heart is finally arrested. Hypodermically injected, the pulse-rate is increased with diminished arterial pressure and diminished pulse-curves. Large doses paralyze the heart (Schonten, loc. cit.; Eulenberg and Guttman, Virchow's Archiv, xli., 1867).
Nervous System: Cerebrum.—Consciousness in the higher	*Cerebrum, Spinal Cord and Nerves.*—"The evidence is, I

mammals present until near death. *Spinal Cord.* — The *sensory portions* of the spinal cord are the first portions of the reflex apparatus to be paralyzed, and reflex paralysis is due to this cause. The *motor* portions of the cord are als depressed, as well as both the *sensory* and *motor nerves.*

think, sufficient to prove that bromide potassium affects all parts of the nervous system of the lower animals, but that the cerebrum, the motor tract of the cord, and the efferent nerves, are the last portions to be affected; that the most sensitive is the receptive (sensory) portion of the cord . . . and next to this are the peripheral ends of the sensory nerves." (H. C. Woods' Therapeutics, 1879, p. 825.

Muscular System. — The muscular system is depressed.

Muscular System. — Depressed. (Papers quoted.)

In small and repeated doses the remedy acts upon and relieves what is termed pulsating tinnitus, but in true labyrinthine tinnitus it has but little influence, not acting as an emunctory either of the skin, glands, or kidneys. The dose is fifteen drops of the strong acid well diluted, but with care it can be increased to sixty drops; it should always be given in an abundance of syrup and water, and to prevent dyspeptic symptoms should be combined with a bitter tonic, etc.

(*To be continued.*)

NON-SPECIFIC FUNGOID GROWTH OF THE VULVA.

BY T. WALLACE SIMON, M. D.,

Of Philadelphia.

On the 3d of June, 1884, I was called to see Mrs. McK——, a young woman, recently married (about a year), not yet pregnant.

I, and my father before my time, had attended her and her husband, and both their families, and there was no trace whatever of constitutional or specific syphilitic history in either family.

Mrs. McK——, a bright, healthy, and intelligent young Irish woman, aged nineteen, complained of what she called an eruption on the "privates," with great pain in copulation, with soreness, itching, and burning pain after the act, and a smarting, burning pain in micturition. Her husband also corroborated her statements, and said that the eruption she complained of made their sexual relations both painful and unpleasant.

On examination, I found both the greater and lesser labia completely covered with a fungoid growth, racemose in character, running down to and past the fourchette, on to the anus. It was blood-red in color, and grew as thick and close as cauliflower, very much resembling the latter in its form and shape. It grew as high from the surface as one-quarter of an inch; and on separating the tufts of the growth, an apparently healthy skin was disclosed below.

This seemed to me a very unusual case. I searched my library in vain for a parallel, and came to the conclusion to treat it in my own way. Here was a great mass of fungoid, mushroom growth, reaching from the mons veneris all the way down to the anus, and extending beyond the labia, somewhat on the thighs on either side.

First, I attempted (with Drs. S. C. McClure and Isaac Barton in consultation) the laborious task of separating each tuft and ligating at the base, hoping to strangulate it, but found it would not answer the purpose. Nor would it have been possible to cut off the growth with the knife close to the surface. So I adopted the following plan, which, it seems to me, was unique in itself, and which I have not seen described in any work on tumors or adventitious growths of this part, and I think should merit recording.

On my next visit to the patient, I took a stout pair of forceps—the teeth of which fitted perfectly down to the point, which was rather broad and flat at the end—and went over the greater part of the growth at the first operation, pinching each separate tuft of the growth, down at the surface of the skin, until I could feel the teeth of the two blades of the forceps "grit" together, thus practically strangulating the growth and cutting off its blood-supply. The tufts did not come off with the forceps, but hung loose and pendulous after the nipping process. This was almost entirely bloodless.

I then painted the tufts that I had strangulated with a mixture of Monsell's solution and iodine. In three operations I had strangulated all the growth in this way, and in a few days the growth had nearly all dropped off on the napkins the patient wore, and in about two weeks there was a clean surface of healthy skin without a vestige of the growth remaining.

Within one year from the time of the operation I delivered Mrs. McK. of a fine healthy child, and there was then no trace whatever of the old growth, or any sign of a return of it, the skin being perfectly clean and healthy. no scar remaining.

I scarcely know what to term such a growth. If it was a *non-specific adenoma*, I do not remember having heard of, nor have I seen recorded, a similar case.

—A citizen of Iona, Mich., while standing with wet rubbers on an iron doorstep, suddenly lost the power of walking. He nearly fainted from terror, thinking he was paralyzed. Upon discovering that his rubbers were frozen to the doorstep he felt better.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

(*Concluded from page* 365.)

Dr. Longaker thought it far better to turn the fœtus by the bipolar method before rupturing the membranes or perforating the placenta. He had attended a lady in her first labor at the age of thirty-seven years. She was seized with profuse hemorrhage while walking in the street. When called, he found placenta prævia; the os was open to the size of the index finger, and large clots were in the lower segment of the uterus. He turned the child by the bipolar method, passed two fingers through the placenta, brought one leg through and left the case to nature. The child was lost as the entire placenta was attached low down, placenta prævia centralis, and retraction of the uterus, interfered with utero-placental circulation. In a second case, turning was followed by a similar result in a case of placenta prævia centralis. While the two children were lost, both mothers recovered without an unfavorable symptom. In three cases, respectively of lateral marginal and partial placenta prævia, treated by rupture of membranes, and application of forceps in one of them, two children were lost. In one of these cases the fœtal heart-sounds were extinct on my arrival, half an hour after a sudden and profuse hemorrhage. All the mothers did well. The high fœtal mortality shows that we cannot place much value upon the child's life, and in view of the dangers which threaten the mother's life, would it not be best to interfere promptly when called to a case of hemorrhage from this cause regardless of the age of the fœtus?

Dr. M. Price inquired of Dr. Longaker how the feet could come through the placenta unless he first passes his hand through to make a hole? When the thighs and breech come down they serve the purpose of an efficient tampon.

Dr. Longaker replied that version being first accomplished, the hand is passed into the vagina and two fingers through the placenta can find the foot.

Dr. H. A. Kelly exhibited a placenta prævia centralis of the seventh month of pregnancy, in which he had perforated the placenta to break the amnion, and after turning, delivered, saving the mother, who had suffered from profuse hemorrhages. He described a case in which turning had proved impossible in a placenta prævia lateralis owing to the fact that the cord was so tightly wrapped around the child's neck that only a small bight was left between the head and placenta, and when the foot was brought out at the vulva the head was felt fixed at the brim as at first. The foot was returned and a forceps delivery of the head revealed the difficulty, which was corrected, and the mother delivered of a seven-months' baby, which died immediately. The mother made a perfect recovery. No one rule suits all cases. The first point of importance in event of free hemorrhage is to rupture the membranes, and this must not be a mere fracture, but as free a separation as possible along the placental margin. The hemorrhage comes from the separation of the uterine and placental surfaces, and this is only to be prevented by freeing the placenta on one margin so that as the contraction ring goes up, the placenta may, as far as possible, ascend with it. Turning is only needed in the more urgent cases. Where the pains are strong and the hemorrhage has been but moderate, let the head engage and more children will be saved.

He urged more care in the classification of cases, for when the diagnosis is made early through an os but moderately dilated, and placental tissue felt every where, the diagnosis of a central implantation is often made, which attention to the later development of the case will show, through a fully-opened os, to be partial.

The tampon, also, should be given up, for, unless scientifically applied, it is utterly useless; it introduces great danger of sepsis, and with the best applied tampon in the absence of the necessary counter-pressure above in the uterus, in the very cases in which it is used, the dangers of concealed hemorrhage are imminent. If the bleeding has been great, bring on active labor, but don't use the tampon. Finally, and most important, every case should be treated by thorough antiseptic measures owing to increased septic susceptibility.

Dr. Parvin remarked that the classification of placenta prævia that had been given was incomplete; it did not include all the facts, for instead of two there are four varieties of the disorder. Thus we have not only central and partial, but also marginal and lateral implantation of the placenta when this organ is prævia; and it is prævia whenever it occupies a portion of the womb, which must be dilated to permit the passage of the child. Manifestly, the results, both as to maternal and fœtal mortality, will be very different in different varieties.

It is a mistake to assert that the tampon treatment of placenta prævia has been abandoned. Very many eminent French obstetricians, for example, in certain cases, employ the tampon, and the cases will be referred to again. That the tampon permits concealed hemorrhage is an old objection which has gained nothing by time; it is a sort of bugbear that does not frighten obstetricians who have used the tampon, for where it is properly applied, the membranes being unruptured, bleeding, either internal or external, to any serious amount, is impossible. Indeed, if the uterus be properly compressed through the abdominal wall, and the tampon well applied, serious hemorrhage from placenta previa, even after the rupture of the membranes, is impossible. That septicæmia is peculiarly liable to occur in cases where there has been placenta previa has been for some time generally recognized, this liability arising, not from the position of the placenta, but from the manipulations, the consequence of such position.

Now in violent cases of hemorrhage resulting from placenta prævia is the tampon advisable? Blundell has stated that in one night he was called to two women far advanced in pregnancy, both dead from uterine hemorrhage, and then refers to some cases of such flooding where removal of the child could be more readily effected by the Cæsarian operation, so slightly dilated and so resistant was the os uteri. The most natural treatment of a hemorrhage occurring with an undilated os is arrest of the flow by pressure, that is by the application of the tampon; such treatment may be available in some cases where no other can be so readily applied. We are indebted more especially to Wigand for the first clear and complete exposition of the tampon treatment in placenta prævia, and his testimony as to the value of his method, first uttered probably one hundred years ago, was very strong, for he declared that in suitable cases and properly used, no death of mother or child occurred. Müller, whose elaborate monograph upon placenta prævia is so well known to those who have studied this subject, has given a qualified but still a positive endorsement of the tampon as the proper means to employ in certain cases and at a certain stage of the hemorrhage, that is when the cervix is undilated. There have been cases in the hands of both Pajot and Bailly, left, as was Wigand's practice, after the thorough tamponing, to nature, the further progress of the labor being undisturbed by art. Murphy has been the most successful among recent obstetricians in the treatment of placenta prævia; and his method is the induction of premature labor, with partial detachment of the placenta and the use of Barnes's dilators. But it is to be observed that the dilators act as tampons by their pressure arresting the flow of blood. Certainly the remarkable success which has attended Murphy's method in his own hands, especially the low maternal mortality which he has secured, speaks strongly in favor of the general adoption of that method. In reporting cases of placenta prævia it seems to me very important, in order that we may compare similars, to know the variety of the disorder in each instance. The practitioner who, for example, successfully for both mother and child, conducts a case of lateral implantation of the placenta has accomplished no wonderful achievement. We cannot arrive at a certain knowledge unless the materials for induction are properly classified. One word more. Some skepticism has been expressed as to the possibility, or rather practicability of combined internal and external version in cases of placenta prævia; but as this has been accomplished, it is hardly a question for discussion.

Dr. Price's cases were at full term. He had not taken premature cases into his account. Deliveries at five, six, and seven months, the fœtus not being viable, admit different principles. Emptying the uterus as early as possible is safer for the mother.

Pelvic Measurement.

Dr. H. A. Kelly called the attention of the Society to an external direct method of measuring the conjugata vera which he had found of extreme value in a large number of non-pregnant gynecological cases which had come to him complaining of difficulties since a previous confinement.

The short vagina or cellulitis or cicatricial contractions often prevent the finger in the vagina from reaching the promontory. In a case he had examined in the morning, the short vagina prevented the vaginal finger reaching the promontory while the outside hand rested upon it, and on pressing deeper felt the vaginal fingers fully three centimetres below. This case was measured by the outside hand, and determined normal. Another case had a rachitic pelvis 8½ centimetres conjugate. She had borne ten children at term through difficult labors, but without assistance.

The method is simple, avoids a vaginal examination in the virgin, is invaluable in many cases retrospectively and prognostically. The inaccuracy of the external con-

jugate is well known. This, of course, is of no use in the most important class of cases, the advanced pregnant, but it does often afford invaluable facts in other cases.

The method is to press deeply with the finger-tips of the extended hand until the promontory of the sacrum is felt, then by slipping the fingers up and down over this until the relations are well appreciated, let the fingers rest vertically above the angle, and at the same time mark on the palm with the finger of the other hand the position of the posterior surface of the symphysis, also vertically below. This measurement from the mark thus made to the tip of the finger is the conjugata vera thus directly measured.

Dr. Montgomery, in a paper entitled **Tracheotomy and Intubation in Diphtheria**, urged the importance of early operation. The symptom which should indicate the necessity for operation was depression of the substernal region during inspiration. This symptom indicates the inefficient entrance of air to fill the lungs, and the diaphragm becomes a fixed point depressing the soft tissues. The longer this condition continues the greater the danger of collapse of portions of lung tissue. The large mortality after tracheotomy and intubation is due to the postponement of operative interference in the majority of cases until these changes have occurred. This assertion is verified by his own experience in tracheotomy. In his first ten cases, in all but one of which the operation was done as a last resort, none recovered. In the next seven cases in which excepting two, it was done early, five recovered. The two fatal cases were not considered hopeful at the time of operation. His eighteenth case died before the trachea was opened. Of the last ten, five recovered—twenty-eight cases, with ten recoveries. He has practiced intubation in thirteen cases with six recoveries. All but one of these cases were seen in consultation, and some of them were in a dying condition when intubation was practiced. In no case did death occur in less than twenty-four hours, and in all the relief from dyspnœa was prompt and permanent. The youngest child was eighteen months of age, and died on the fifth day of convulsions. The youngest child to recover was æt. two years. In one case of recovery tracheotomy was performed the day following the intubation. A smaller size tube than suited for its age had been used; the dyspnœa recurring, and the tube absent from the glottis, it was feared that it had been passed into the trachea. It was found that the tube was coughed up and swallowed and passed per anum two days later. Of course in this case little can be claimed for intubation. He prefers intubation to tracheotomy, and believes that the former will supplant the necessity of doing the latter. The advantages are: it is free from danger, it requires no cutting nor anæsthetic, the after-treatment does not require skilled attention, as the air is moistened and warmed by the natural passages before entering the trachea, there is therefore no dry mucus accumulating in the tube, and not the same danger of secondary inflammatory lesions. As the tube does not fill up the calibre of the trachea, membrane is coughed up around instead of through it, and thus the danger of blocking is avoided.

Dr. Joseph Price presented to the Society a framed engraving, a portrait of Dr. Emmett, of New York.

W. H. H. Githens, *Secretary.*

THE NEW YORK NEUROLOGICAL SOCIETY.

Stated meeting, February 1, 1887. The President, C. L. Dana, M. D., in the chair.

Dr. C. L. Dana reported a case of

Pachymeningitis Hemorrhagica, with Large Meningeal Hemorrhage Pressing Chiefly on Leg Centre—Right Hemiplegia, Total Paralysis in Leg, Aphasia, Hemi-anæsthesia, Convulsions Limited to Arm and Face—Death—Exhibition of Specimen.

The patient was a woman about sixty-eight years old, and came into the hospital with complete motor aphasia, and unable to give any previous history. She had no paralysis at first; but three days after admission she had a general convulsion, followed by right hemiplegia; total in the leg, and some right-sided anæsthesia. On the second and third days she had a series of brief localized convulsions involving the face bilaterally and the right arm. These were carefully observed. The movements were clonic, beginning in the muscles of the lower jaw. The other peculiarities were these:

1. The pupils remained small during the convulsions. When wider convulsive centres are discharging, as in general epileptic convulsions, the pupils are dilated. It is not probable that in this case there was some uræmic element, because the post-mortem disclosed a sufficient cause for them.

2. The conjugate deviation of the eyes was at first, and very temporarily, toward the side of the lesion, and away from the paralyzed side. The head, also, was turned toward this side. When this occurs, it is ordi-

narily spoken of as a paralytic deviation. This does not explain it here since almost immediately the head and eyes were turned strongly to the opposite and paralyzed side.

The speaker suggested that the first deviation is due to an inhibition of the activity of the associated nuclei of the third and sixth nerves that innervate the external and internal recti of the two eyes. There are many facts which tend to show that the first stage of convulsion is a transient paralysis due to a sudden discharge of inhibition centres. These are of a higher, more developed class than the centres for motor discharges, and would be affected first. We would have then, loss of consciousness, inhibition of motion, and muscular relaxation; then motor discharges and tonic and clonic convulsions.

3. The temperature on the paralyzed side was one degree higher than normal, and higher by a degree than that of the other side. This is the rule in intra-cerebral hemorrhage and hemiplegia, but the speaker was not aware that it has been established in cortical hemiplegias. In meningeal hemorrhages the temperature is often below normal according to Minot.

4. The presence of hemi-anæsthesia.

The patient died on the third day. Post-mortem showed chronic pachymeningitis over both convexities, but more on the left side. On the left convexity there was a very extensive fresh meningeal clot pressing upon and flattening especially the upper half of the central convolutions. Brain substance normal.

Cortical Epilepsy with Temporary Asphasia. Syphilitic Gumma Compressing the Left Second Frontal Convolution in Its Lower Posterior Part. Recovery.

Dr. M. Allan Starr related the history of the case. Charles S., aged thirty-two, had always been healthy and a hard worker. He had an attack of sciatica four years ago, and three years ago had a hard chancre. He had never had convulsions or nervous affection. Family history good. During November, 1886, and the first two weeks of December, he did not sleep well, was slightly dizzy, his head ached a good deal, chiefly at night. December 15, while walking with a pail in his right hand, he suddenly let it drop, losing all power in the hand and arm. There was numbness in the hand. He was unable to speak to his companions. He did not feel dizzy or notice any pain in the head; he did not lose consciousness nor fall. He understood his friends' questions, but could not answer. Power in the hand and arm, and speech returned within half an hour. The next morning he went to work, as well as usual. Two days later a second attack occurred, beginning with a numb feeling in the tips of the fingers, gradually extending up the hand and arm. Then the fingers became rather forcibly flexed and stiff, but by a voluntary effort he could straighten them. No clonic spasms of the fingers, and wrist and elbow were not bent. The numbness and stiff feeling soon extended to the face, which was drawn to the right side with some force. Speech was again lost. No loss of consciousness. The attack lasted about twenty minutes. Such attacks had occurred every other day, then every day, and finally twice a day up to January 3, and during this time the headache and insomnia were increasing steadily. The character of the attacks was not uniform. Sometimes the spasm would begin in the face, though usually the arm was first affected. Both were involved in every attack, but the spasm and numbness never reached the leg. The hand felt cold during an attack, though warm to the touch. On one occasion he had for four days great difficulty in making himself understood by words. Examination by Dr. Starr showed slight paresis, and slight tactile anæsthesia in right hand, no affection of face or speech. No cardiac symptoms. Though suffering from headache, percussion of skull did not reveal any tender spots. Thrombosis, endarteritis syphilitica, diffuse encephalitis with sclerosis were excluded, and the diagnosis was reached of gumma in the membranes, resting upon the brain surface, giving rise to irritation and consequently to an occasional nervous discharge, but not of sufficient size to cause any destruction. Location of tumor was equally clear; the relative situations of the cortical centres for the arm, face, and for the movements of speech in the lower two-thirds of the anterior central convolution, and in the posterior part of the third frontal convolutions were likened to a reversed ⅃. All these centres were irritated during the attacks, the irritation sometimes beginning in one, sometimes in another. If the tumor pressed upon the lowest posterior part of the second frontal convolution which would lie inside of the ⅃, an irritation radiating from it might reach all three centres equally. The total intermission of the local symptoms might be explained by such a location since no symptoms were known to occur from injury of this part. The fact that numbness in the hand and face uniformly accompanied the attacks of spasm seemed to indicate that

the areas for these parts coincide with the motor areas.

Another point of interest was the distinctly motor character of the aphasia.

The treatment ordered was first inunction of mercury, and second iodide of potash daily in divided doses. He had one attack two days after beginning treatment, but since that time he had had no return of the symptoms. Iodide of potash was still being taken.

DISCUSSION ON DR. STARR'S PAPER.

Dr. Seguin had seen several cases whose symptoms resembled those of the case recorded in Dr. Starr's paper. The prognosis of even non-syphilitic cortical lesions with this symptomatology was not absolutely unfavorable. One of the cases to which he referred was that of a Cuban who came to his clinic about nine years ago. He had never had syphilis, yet he described epileptic attacks of the true cortical kind, such as have been obtained by experiments upon animals during the last few years. The hand would become numb, and then the seat of a vibratory sensation; finally contraction would occur in the hand, when the face, and almost simultaneously the leg, would be affected, and he would lose consciousness. According to his friends' account, general convulsions then occurred. He had had quite a number of these seizures; yet examination showed no anæsthesia, no affection of the optic nerve, and, so far as the speaker could recollect, no motor impairment. The patient had received a preparation composed mostly of the bromide of potassium, to which a little of the iodide was added. He improved immediately, and four weeks ago the attacks ceased. Once in a while he has the sensation of wires in the hand, and the hand becomes stiff, but the face is never affected. The case was a beautiful illustration of the localization of a lesion in the centres for the hand, the discharge radiating to those of the face and leg of the same side, then to the opposite side, with loss of consciousness.

The patient had also been the object of the bracelet experiment. He was a powerful man, and had exerted great force, arresting many attacks in this way. The speaker was satisfied that syphilis was absent, while the amount of the iodide was too small to explain a cure upon the ground of a syphilitic affection.

Dr. Starr had been much interested in the case which Dr. Seguin had related. He had recently had a case of unilateral convulsions in his office. The patient was a small boy. The attack commenced in the eyes and face. The eyes turned to the right, then the head turned to the right; then the arm, then the leg became affected. During the attack the speaker had asked suddenly, "What is your name?" The boy promptly replied, "Arthur," and then relapsed into the convulsion. He supposed that the reply was reflex, as the boy was unconscious at the time, and did not afterward remember the occurrence. He would like the opinion of the members upon the point.

Dr. Dana asked what Dr. Seguin had considered the lesion in his case.

Dr. Seguin had never ventured to surmise beyond the fact that there was a nerve-lesion and that there was no syphilis in the case.

Dr. Starr asked Dr. Seguin whether in localized convulsions numbness were not the rule.

Dr. Seguin replied that it was; but he did not know that the reason was yet sufficiently established, although Von Monakow had associated anæsthesia with lesions of the motor zone.

Dr. Shaw referred to a case seen first four years ago. While at work as a jeweler, the patient fell off his bench in a convulsion. The face and the left arm were convulsed; the leg was not affected. Sometimes only the side of the face was affected. He had seen many of these attacks limited to the side of the face in his office. The patient complained of numbness in the arm and the side of the face, and the speaker felt sure that the tactile sensibility was not as good upon that as upon the other side. The patient denied syphilis. Upon ophthalmascopic examination the nerves were found pale, and the visual field restricted in its upper part. There was no change until about six months ago, when, without loss of vision, he was found to have choked disk. This had gone on to atrophy, and the man was now blind. There was no paralysis. From the choked disk, of course, the speaker had now diagnosed a tumor, but he referred to the case on account of the anæsthesia and the spasms, and their resemblance to those in Dr. Starr's case.

Dr. Sachs referred to the case of a man who, some years ago, while working upon the Capitol at Albany, had fallen some distance, was found unconscious, but recovered. A few weeks later he developed symptoms which alarmed his friends, and he had now some of the physical, and nearly all of the mental signs of general paresis—the irregular pupils, the facial tremor, the tremor of the tongue, and the deteriorated mentality.

The speaker referred to the case because of the traumatic incident, and because every three or four weeks this man had an attack of numbness, beginning in the fingers and creeping up the right arm to the face. There never were convulsions, but both the patient and his wife, who is a very intelligent person, say that there is paralysis. After three or four hours both the paresis and the numbness disappear, and he has a very severe headache, lasting one or two days. The speaker thought there was a question of chronic meningitis with encephalitis possibly in this case. It was evidently a cortical affair.

Dr. Dana thought that cortical epilepsy might develop like idiopathic epilepsy without an appreciable lesion. He recalled a case, that of a young man who was kicked in the front of the thigh by a horse. Twitching of the leg developed, similar to that of cortical epilepsy. Thrilling and numbness of the arm and face followed. In a year true hemiepileptic attacks, during which he lost consciousness, developed, and upon giving him ether for stretching the nerve he went into the status epilepticus. There was no history of syphilis. Apparently cortical epilepsy was developed just as true idiopathic epilepsy in other cases.

Dr. E. C. Seguin read a paper entitled

A Contribution to the Pathology of the Cerebellum.

A detailed account of one case was given, and specimens, gross and microscopic, illustrating its pathological anatomy, were shown. Three other cases of cerebellar disease were briefly presented, as card specimens with their anatomical demonstrations. The following is a summary of case 1: Male patient, forty-five years old at time of death; a retired officer of the United States navy. Eighteen years before health illness began with headache (not strictly occipital), and one or more seizures of an epileptiform or apoplectiform character. These were followed by impaired vision and more or less continuous headache (fronto-occipital). Later appeared nystagmus and typical cerebellar titubation; slight slowness of speech. There was no distinct paralysis, ataxia, anæsthesia, vertigo, or mental impairment. During several years, from 1877 to 1883 or 1884, the only symptoms were slight frontal headache, defective vision, partial atrophy of both optic nerves, nystagmus of varying form, slight slowness and indistinctness of speech, increased patellar reflex, and titubation.

In February, 1885, an epileptiform seizure left behind it partial left hemiplegia without contracture and anæsthesia. Death on 22d of April, 1885, preceded by a set of distinctly bulbar symptoms; increased dysarthria, dysphagia, salivation, polyuria, also increasing stupor.

Lesions.—Cyst of cerebellum destroying the claudo-ventral part of the middle lobe (not involving the frontal third of the vermis superior), penetrating into the right lateral lobe as far as the nucleus dentatus, not destroying it, and probably exerting only slight pressure upon the floor of the fourth ventricle. There were also found:

1. A small hemorrhagic focus 2 mm. in diameter, in the ventral half of the pons on the right side, in the midst of the pyramidal fasciculi. This explained the left hemiplegia, and from it could be traced a complete descending degeneration of the right pyramidal tract into its subdivisions in the spinal cord.

2. Very extensive arteritis obliterans of the encephalic vessels, causing numerous, mostly symmetrical, foci of softening in the cerebral hemispheres. The only system degeneration which could be traced to the loss of substance in the cerebellum were a moderate reduction in the size of the opposite (left) olive, and partial atrophy of the right rectiform body.

The author called attention to several conclusions to be drawn from a study of these four cases.

1. As to diagnosis. Tumors of the cerebellum produce very variable symptoms, but one symptom, viz., cerebellar titubation, is, as claimed by Nothnagel in 1876 or 1877, pathognomonic of a destructive lesion of the middle lobe of the cerebellum, more especially its caudo-ventral masses. In Dr. Seguin's cases optic neuritis or atrophy had not failed, which was in marked contrast to his experience with tumors of the cerebral hemispheres, which do not usually cause lesion of the optic nerves (1 : 5 or 1 : 4). Vomiting was a frequent symptom; occipital headache and rigidity of muscles of the back of the neck were less frequent but very valuable symptoms.

2. As to therapeutics. Three of the patients had obtained repeated relief from serious symptoms; paroxysms of headache, vomiting, and epileptiform attacks, by the use of the iodide of potassium in doses of from thirty to sixty grains three times a day.

3. As to prognosis. Two of the patients did not die of their cerebellar disease—both cysts—but of complications. Case 1 of dif-

fused arteritis obliterans and consequent softening in various parts of the brain, including impaired nutrition of the bulbar nuclei. The other case, No. 2, of an acute tubercular meningitis. Consequently, we may hope in a few cases to cause or to witness an arrest of the cerebellar disease. The disorder in voluntary movements and the already developed lesions of the optic nerves are, of course, irremediable.

DISCUSSION ON DR. SEGUIN'S PAPER.

Dr. Bradner spoke by invitation. He had been the attendant in the case of the child to which Dr. Seguin had referred. He had not prescribed the washing out. It had been done by a prominent physician of the place. He had done it a number of times during three weeks, but had then refused, believing that the child had brain disease of some form. He saw the patient first in November. The vomiting was always in the morning. There was no pain connected with it then, although a frontal headache had developed during the last few months. The treatment prescribed by Dr. Seguin had been the iodide of potash, fifteen grains, t. i. d., increasing five grains daily, until one hundred grains were taken at a dose. The course had been interrupted by several attacks of acute gastritis, but the child had had those attacks previously; they did not appear to depend upon the medication. The eyesight has been perfect; the child could detect the smallest point made by a lead-pencil or needle. While using the iodide, his headache had improved, as had some other symptoms, but he retained his old man's gait.

Dr. Seguin remarked that, though seeing well, the child had typical choked disk.

Dr. Bradner added that since seeing Dr. Seguin, he had obtained a history of injury in the case. Two years ago, and just before the commencement of his illness, he had, while trying to skate, fallen, and received a severe blow on the back of his head. One result of this injury had been abiding terror at the sight of a body of water or ice.

Dr. Shaw had shown a child at the American Neurological Association in 1878 on account of a peculiar ataxic gait, like that of locomotor ataxia. The later symptoms had pointed to a tumor of the cerebellum.

Dr. Putnam Jacobi referred to the recent collection of cases by Bernhardt. All cases published previous to 1884 had been collected by Nothnagel. Dr. Seguin's cases tended to confirm Nothnagel's laws. There were many resemblances between the symptoms of cerebellar tumor and those of tumor in other parts of the brain. The peculiar violence of the headache and the choked disc found in most cases of cerebellar disease might, she thought, be due to the increased pressure of a tumor confined by the tentorium. This element had not been commented upon, and she would like Dr. Seguin's opinion upon it.

Another point referred to the fact that the laws formulated by Nothnagel recognize the possibility of complete latency of the tumor, no symptoms at all being present when but one lobe of the cerebellum is affected, such symptoms appearing only when the tumor encroaches upon the central lobe. In one of Dr. Seguin's cases the tumor only occupied the lateral lobe. Of course an indirect affection of the central lobe might be present even in such a case.

Dr. Leszinsky referred to a case to which he was called in consultation by Dr. Alexander. The boy had the typical gait of spastic paraplegia; any attempt to stand caused spastic contractures in the limbs, ankle clonus was present, and the knee-jerk was exaggerated. There were no cerebral symptoms; the fundus was normal in both eyes. The father and mother were both alcoholic and unworthy people. Finally the child became unable to walk, but there were still no cerebral signs; no vomiting. Two months before death the fundus was still normal. Later tremor developed, and paralysis of the abducens, and of the fifth and of the third nerves. Total blindness occurred. The nurse, a graduate of Bellevue, was positive that the child could see nothing. It died in a convulsion. Unfortunately, the body was immediatly frozen, and the specimen was unfit for sections. The tumor was found occupying one side of the cerebellum. The spinal cord was not fit for examination. There was a well developed meningitis, and the paralysis was accounted for by considerable exudation about the cerebral nerves. One peculiarity has been a subnormal temperature during one stage of the case.

Dr. Starr had had occasion some time ago to make a collection of cortical lesions from American literature. He had at the same time made a collection of cases of cerebellar disease from the same sources. As the data obtained but corroborated Nothnagel's results, he never published them. But Dr. Seguin having remarked upon the value of corroborative evidence, he would briefly refer to them now. From 1860 to 1884 one hundred and sixty cases of cerebellar disease were reported in American literature. In

only forty of these were the symptoms and the autopsies described with sufficient accuracy to warrant conclusions. These forty the speaker had quite thoroughly analyzed. In four there were no symptoms; in one of these there was congenital atrophy of the cerebellum, in two abscess, and in one a large cyst. Of the remaining 36 presenting symptoms there was headache in 36; incoordination in 25; vertigo in 20; vomiting in 18; blindness in 14; dim vision in 6; diplopia or strabismus in seven; deafness in 7; facial spasm or paresis in 4; hemiplegia in 9; general paralysis in 4; mental symptoms in 8 (stupid 7, mania 1); convulsions in 7; sexual desire increased in 2. Males, 23; females, 17. Ages: between one and twenty years, 11 cases; between twenty and forty years, 16 cases; between forty and sixty years, 9 cases; over sixty years, 1 case; age not stated in three.

In two of the eleven cases in which incoordination did not occur, the lesion probably involved the middle lobe. In cases where incoördination occurred various parts of the cerebellum were involved, but the probability was that the middle lobe was affected in the majority. There were only two instances of increased sexual desire. Bernhardt had found but one instance in ninety cases of cerebellar tumor, and Nothnagel but two cases. The speaker thought that it might be thrown out as a symptom of cerebellar disease, and regarded as one of accidental occurrence. The escape from vertigo in Dr. Seguin's case was explained perhaps by the recent discoveries in the anatomy of the course of the acoustic nerve. This nerve served for the sense of hearing and the sense of space. The centre for hearing is in the pons. Edinger finds the centre for equilibrium in the cerebellum, to which acoustic fibres pass by way of the middle peduncle. From this centre the central tract probably passes onward to the superior peduncle. Dr. Seguin says that the superior peduncle escaped in his case. It is therefore natural that vertigo should not have occurred.

The tendency to rotation was an interesting feature in these cases. There was a tendency to fall or turn forward in two cases; the lesion was in both a tumor in the vermis, in the anterior part. There was a tendency to fall to the right in two cases, in one there being a tumor in the left middle peduncle, and in the other an abscess in the same part. There was a tendency to fall to the left in two cases, in one there being an abscess in the right middle peduncle, and in the other a tumor in the left middle peduncle. A patient of Nothnagel, whom the speaker had seen in Vienna, when getting up in bed, had always a tendency to turn to the right side. Nothnagel considered this due to vertigo. It was only present when the patient was erect. The patient felt as though about to fall to the left side, and hence turned to the right. This case had a tubercle of the left middle peduncle of the cerebellum. Nothnagel considered this symptom only produced by affection of the middle peduncle. In the two cases in the table where the tendency was to turn to the right there was disease of the left middle peduncle, while in the two in which the tendency was to the left, in one the right peduncle and in the other the left peduncle was affected. No rule can, therefore, as yet be laid down as to the cause of this symptom.

Dr. English had had charge of the case which formed the subject of Dr. Seguin's paper, and he congratulated the Society upon the progress which had been recently made in the diagnosis and treatment of cerebellar disease. Early in 1878, Dr. Seguin had written him a letter, accurately diagnosing this case, as seen on autopsy.

Dr. Seguin closed the discussion. He was not surprised to learn of the little boy's fall, as he was a firm believer in the traumatic origin of these conditions. It was very difficult to obtain a history of fall. He could not give an opinion upon the question propounded by Dr. Putnam Jacobi. In regard to ascribing the vertigo to the acoustic nerve, he was not yet certain that the acoustic nerve had cerebellar origin. He thought it would be difficult to trace fibres through the lateral peduncle of the cerebellum, the vermis, and the anterior peduncle.

He said Dr. Starr had probably made a mistake when he referred to Nothnagel connecting rotation with disease of the middle peduncle. Middle vermis he had probably meant to say.

Dr. Starr accepted the correction.

How He Released the Finger.

A Western contemporary tells a story illustrating the oft-repeated truth that the surgeon cannot afford to neglect applied mechanics and physics: A young lady had her finger caught in the valve of an air-gun. A physician being called, after careful consideration, decided that the only means of releasing the finger was to amputate it. This being done, the gunsmith arrived, and proceeded to release the amputated finger by boring a hole in the chamber of the gun.

Sudden Death from Nightmare; Some Reflections on the Cause, Treatment, and Prevention.

Dr. Matthew Turner thus writes in the *Alabama Medical and Surgical Journal:*

S. B. C., aged thirty-five years; male; white; married. Native of Alabama. By occupation a farmer.

The subject of this sketch was a young man in full health, of steady habits, used no narcotics or stimulants, and took a great deal of out-door exercise; was seldom "ailing," and, except a mild attack of dysentery and an occasional chill during the summer, was never sick. He was one of a pair or twins, the stouter and more handsome of the two, and was a perfect type of a healthy man in mind and body. He was of nervous temperament.

About the latter part of August, Mr. C. was surveying some land on the river for the purpose of settling a boundary line between him and some neighbors, when he discovered, near the line, a mine of some mineral, supposed to be of immense value, and, like most men under such circumstances, saw visions of fabulous wealth almost within his grasp. Fearing a difficulty about the division, he spent the next day in visiting parties interested, and underwent a great deal of fatigue and a proportionate amount of anxiety. About 8 p. m., he held an interview with the last party concerned, and greatly to his relief found no obstacle in his way to a big fortune—the land was his, and no one was disposed to dispute his title.

Instead of remaining that night, as he expected, from home, he was so much elated at his success that he rode home, ten miles, to communicate his good fortune to his family, who shared in his anxiety.

On reaching home, his wife, not expecting him at that hour, had retired and made no provision for his supper, but told him there were some cold dishes in the closet. Of these he made a hearty meal, having gone without his dinner, and, after talking over the events of the day with his wife, still under great excitement, he retired.

This was about 11:30 p. m., and about thirty-six hours from the time the excitement commenced about the mine. About 5 o'clock the next morning his wife was awakened by his distressed groaning, and, supposing that he was suffering from "nightmare," shook him and aroused him sufficiently to cause him to move himself in bed, and the groaning ceased, and he seemed to drop into a quiet slumber.

Knowing that her husband had been unusually excited and fatigued, his wife quietly got out of bed and adjusted the bed-clothing, with the hope that he might have a quiet nap while she was preparing breakfast. Passing through the room in about a half hour she noticed one foot uncovered, and, in readjusting the covering, perceived that the foot was very cold. Here she discovered her fatal mistake. He was dead, and perhaps breathed his last when she first left him. Had she known his danger, and persevered in her efforts to arouse him at that time, she would in all probability have been successful, and he perhaps would have laughed at the recollections of a dreadful dream, and never have realized how near the portals of eternity he had been.

Now, what are the chief factors in "nightmare?" In somnambulism we have the power of motion unimpaired, but memory and judgment seem entirely suspended. In "nightmare" sensation and memory are active, but the power of motion is lost. Hence we would infer that the kinesodic area of the medulla oblongata is paralyzed, and that the patient dies from asphyxia or heart-failure.

We are all familiar with the sympathy existing between the stomach and the heart, as well as the physical disturbances resulting from indigestion. The child who habitually screams out at night from frightful dreams will often, when put to bed hungry, with only a cracker and a cup of tea, sleep soundly without any terrors, whereas, if allowed to fill the stomach with heavy, indigestible food, he will not only dream, but may have convulsions added to the regular matinee.

We know that fatal syncope has been brought about by taking a heavy draught of cold water, and that the same result may ensue from purely emotional causes.

It is not so much the object of this paper to discuss the causes and the "modus operandi" in these cases, as to call the attention of the profession to the fact that, notwithstanding they are generally regarded as trivial and attributed to an imprudent supper,

etc., they do sometimes become serious, and terminate fatally.

As a preventive measure, the general health should be looked after, and especially indigestion should receive our first attention. Treatment during the paroxysm is simple. A slap, rude shake, or douche of cold water in the face, will usually arouse the consciousness of the patient, and, under the efforts of the will, respiration and circulation are restored.

I would suggest that such subjects should not sleep alone, but always in hearing of some friend or attendant, who will be on the *qui vive* for the first manifestations of an attack, and apply the means of restoration immediately and effectually.

Ammonia, belladonna, digitalis, *et id omne genus*, hypodermically or otherwise, would naturally suggest themselves to the mind; but in the usual course of the attack the physician would seldom be in at the right time for their application, and only in cases where complete restoration is tardy and the organs hesitate in the full resumption of their functions, would they be of any avail.

Congenital Stricture of the Urethra in an Infant.

To the Academy of Medicine, in Ireland, Dr. Macan submitted a case of congenital stricture of the orifice of the urethra, hypertrophy of the bladder, and cystic degeneration of the kidneys. The specimen was the first of the kind he had met with, and was taken from a full-grown child in the Rotunda Hospital about a fortnight before. The child was suffering from imperforate anus, and soon died. On examining the abdomen over the pubes, after death, a movable tumor was detected, reaching as far as the umbilicus. From the gristly feeling of it, he first thought it was malignant disease of the bladder. The penis was very much distorted in shape, and œdematous. On opening the tumor, it was found to be the bladder, with thick hypertrophied walls. Fœtal urine, clear and limpid in character, flowed out, and, after the gush, the bladder seemed to fill again, and another gush took place. He searched for some diverticulum in the bladder that might be filled with urine, but found none; but, on cutting down more into the bladder, he found that the fresh flows of urine came through the ureters. It was then apparent that there must be a collection of urine in the kidneys. There was great contraction of the urethral orifice, and great dilatation of the urethra. The right kidney was blown out into a cyst, and contained a considerable quantity of urine. The left kidney was also disorganized. The intestine ended in a blind sac at the lower portion of the bladder. He thought the primary source of disease was the occlusion of the orifice of the urethra. The accumulation of the liquor amnii during the later stages of pregnancy was a proof that that fluid was, in fact, the secretion from the kidneys of the fœtus. The child in question presented another curious anomaly. On one side of the spinal column there was a depression of the skin, with a cicatrix on the outside, which was proved to be caused by a spina bifida. There was also a deformity in one of the legs.

The President said the specimen was evidence of a well-known pathological law, in accordance with which several different malformations had a tendency to be associated. He did not gather from Dr. Macan whether he held the opinion that liquor amnii was to be looked on as so much diluted urine, or that it was a different fluid, only contaminated by the fœtal urine. The presence of urea in it was not enough to settle the question.

Professor Bennett said Dr. Macan had not mentioned the condition of the urachus. Urinary fistula at the umbilicus was not uncommonly met with without any other deformity; and imperforate anus also occurred independently of the other things seen in the present specimen. The most important point connected with the specimen in a surgical aspect was that of the limb deformity being associated with an indication of damage to the spinal cord. It would be interesting if an examination of the specimen could be made in order to ascertain the extent of the nervous supply to the muscles of the deformed limb, for at the present day the exact nature of the lesions known as "club-foot," and congenital deformity of the hip, were vexed questions. In the present specimen there was club-foot with a distinct lesion, which might involve the nerves that passed into the limb.

Dr. Wheeler expressed regret that the intestine in the present case had not been dissected further up, in order to ascertain where the closure was. Some years ago he brought forward a case of imperforate anus with an opening in the gut at the side of a spina bifida.

Dr. Thornley Stoker said the occurrence of cystoid degeneration of the kidneys in the fœtus, though rare, was not altogether unknown. The degenerate kidney sometimes attained a considerable size, pressed up the

diaphragm, and displaced the liver into the thorax. It was now a matter of considerable interest to surgeons to arrive at a conclusion as to where the bowel could be best looked for in cases of imperforate anus. The most modern plan was to perform laparotomy, or a lumbar operation, and not to attempt any procedure involving the peritoneum.

The President remarked that in some of the islands of the South Pacific nearly all the natives were afflicted with congenital phimosis, and many of them had a preputial orifice no larger than a pin's head.

Dr. Macan, in reply, said he would hardly recommend that a child's abdomen should be opened in a case of imperforate anus. There were cases in which the operation should obviously be a rectal one. In the present specimen, the end of the gut was at the bottom of the bladder. There was no atresia—only a stricture. A very considerable quantity of the liquor amnii must have been urine, unless the child passed a very small amount of water and drank the fluid. Fœtal urine seemed to be the only known source of liquor amnii, and the fact that the quantity of urea in that fluid was known to increase towards the end of pregnancy seemed to show that fœtal urine was at all events a considerable source of it.

Iodide of Potassium in the Treatment of Diphtheria.

Dr. L. Stepp (*Deutsche Med. Wochenschrift*) recommends mercury and iodine in diphtheria. Mercury has been given in various forms and doses in diphtheria and croup, though without any good results, as, owing to its poisonous properties, sufficiently large doses cannot be given to destroy bacteria in the blood. Its action is only efficacious in syphilis. In diphtheria, on the other hand, the incubation-period is from two to five days, and serious symptoms develop rapidly. Iodine seems to be the only suitable medicine; and probably still larger doses are required in diphtheria than in syphilis. These two diseases resemble each other, in that they both have a tendency to encroach on the bucco-pharyngeal mucous membrane, and thereby affect the neighboring glands. Iodide of potassium is decomposed in the organism, and iodine remains in the blood and other liquid elements, and in the glands, where it amalgamates with albuminoid molecules, and possibly with bacteria; in any case, it sterilizes media in which bacteria develop. Dr. Stepp mentions one case of diphtheria out of many which he has treated with iodide of potassium. The patient, a girl aged 7, who had been ill for three days, had a very thick false membrane in the pharynx, the glands of the neck were involved, the pulse was weak, and the temperature high. Three grammes of iodide of potassium were given in 120 grammes of water. At the end of a week, the child was completely cured. A boy, aged 7, in whom diphtheria had come on three days previously, was treated in the same way. A teaspoonful of the solution was given every hour; two days after the treatment was begun, the temperature was lower, and the general condition better, though there was no apparent change in the state of the pharynx. Twenty-four hours later, the child's condition became alarming; there was cyanosis of the cheeks and lips, the pulse was 140 to 160, and the little patient fell into a condition of complete apathy. No medicine had been given for fifteen hours, as the smell of the iodine had caused nausea. The following mixture was then ordered:

R.	Iodide of potassium,	100 grammes.
	Water,	20 grammes.
	Syrup of orange peel,	20 grammes.

A teaspoonful every hour night and day. Tokay wine was also ordered at intervals.

On the fourth day of the new treatment, the patient's condition was greatly improved, and the pulse was stronger. A teaspoonful of the solution of 5 grammes of iodide of potassium in 120 grammes of water was given. On the fifth day, the temperature was lower, but the swelling of the neck and the false membrane in the pharynx remained unchanged. Eight grammes of iodide in 120 grammes of water were then given in doses of a teaspoonful every hour; on the following day the dose was increased to 10 grammes of iodide. On the seventh day, the false membrane became detached, the cough was looser, and there was less hoarseness, whilst the infiltration of the neck had disappeared. The pulse was 132, the temperature 38.3° C., and the general condition satisfactory. On the eighth day, the temperature rose to 39° C. towards evening, but fell again on the ninth day; the false membranes had disappeared, and the cough was not so hard, though the voice remained rather hoarse. Complete convalescence was established on the tenth day. In the course of one week the child had taken 50 grammes of iodide of potassium. There have been no subsequent symptoms, either as regards the digestive organs or the nervous system.

The Pathological Anatomy of Chorea.

Fatal cases of chorea are not very common, so that every carefully conducted post-mortem examination is of value in aiding to discover the morbid conditions present, and to decipher the pathology of the disease. The opinion is becoming more and more general that chorea is not an entity as a disease; that there are, indeed, several forms, varying in their etiology, to some extent in their symptoms, and in their sequelæ. In a case of chorea minor, which ended fatally by an attack of apyretic pneumonia, Nauwerck made a careful examination of the nervous system, both central and peripheral. He found that the peripheral nerves were normal, but that in the central nervous system there were many changes, all of which were microscopic. He divides these changes into three classes. In the first he includes patches, here and there, of infiltration of the perivascular sheaths by round cells, extending sometimes into the surrounding tissues. This infiltration was most marked in the medulla and pons; there was none to be observed in the spinal cord, the cerebellum, the basal ganglia, or the cortex of the brain. In the second class of changes, Nauwerck describes points of hemorrhage, one to two millimetres long, situated in the cerebral peduncles, the inner capsules, and in the medulla and pons. No capillary emboli were found. In the third class, changes in the nerve-fibres are described; these consisted chiefly in a degeneration which was most marked in the white substance of the cervical spinal cord, gradually diminishing downwards to the lumbar region. Microscopically, the axis-cylinders of the fibres were seen irregularly swollen, in the condition which is known as "hypertrophy;" they stained badly with neutral carmine, and osmic acid showed fatty granules in their interior. In some fibres, the place of the axis-cylinder was wholly occupied by fat-globules. The degeneration of the fibres did not occupy any particular tract of the cord, but was scattered irregularly. Nauwerck considers that the perivascular infiltration of round cells is to be taken as a sign of inflammation; and that it is probable that the degeneration of the nerve-fibres would explain the incoördination of movement in the case recorded by him. A strict search was made for micro-organisms, but none were found in any part of the nervous system. He thinks that there is a group of cases of cholera which may be called infectious, the poison being exclusively localized in the central nervous system.

Uterine Tents and their Effectual Disinfection.

Dr. Dirner, of Buda-Pesth, has recently written in the *Centralblatt für Gynäkologie* on the effectual disinfection of tents used for gynæcological purposes. He observes how, after the greatest precautions, serious pelvic inflammation may follow the introduction of sponge or laminaria tents. This accident is clearly due, not to the mere ulceration of the dilated structures, but to the introduction of septic material through the wounded mucous surface. The preparation of tents by soaking or coating in antiseptic media is insufficient. Septic matter may be introduced with the aseptic tent; surgeons handle and throw about samples at the shops, nor is the process of manufacture always properly superintended. Fritsch's method of coating tents with wax requires warm water to be at hand when the wax has to be melted, and that water may be septic. Dr. Dirner has detected cracks in the wax, allowing the admission of dust. The most carefully prepared dry tents can convey septic germs on their surfaces. For a year Dr. Dirner has employed in Professor Tauffer's wards a special system of disinfecting laminaria tents. He immerses them in a 1 per cent. solution of corrosive sublimate in absolute alcohol contained in a wide-mouthed bottle. When required, a tent is taken straight out of the solution and passed into the canal of the cervix, the patient being previously placed in the semi-prone position, and the vagina disinfected. He takes care to inspect hollow stems before introduction, and should any crystals of sublimate be detected in the channel of a stem, it is dissolved with pure water. The results of this practice have been admirable, and he has seen no bad effects follow the introduction of the disinfected tents; provided that absolute alcohol be employed, the expansive power of the laminaria is in no way damaged.

Koeberle on the Treatment of Uterine Cancer by Hysterectomy.

Professor Koeberlé, of Strasburg, has recently given his views on this subject in the *Nouvelles Archives d'Obstétrique et de Gynécologie*, and they have been ably summarized in the *American Journal of Obstetrics*. He points out that primary cancer of the body of the uterus is very rare. When it occurs, the cervix is not affected for a long time. Cancer of the cervix generally begins near the os externum, and spread thence over the tissues of the cervix, involving the vagina

and adjoining organs, before it passes beyond the level of the os. As long as the disease has not extended to the broad ligaments, or to the lymphatic glands which communicate with the uterine lymphatics, the body of the uterus will be free from malignant disease. Under these circumstances it is not necessary to remove it. When the body of the uterus is the seat of primary cancer, the cervix being sound, it is useless to remove it. Thus, total extirpation of the uterus, whether by abdominal section or through the vagina, is more dangerous and difficult than removal of either the cervix or the body alone. Hence that operation should be reserved for cases in which partial amputation will not suffice for the complete removal of the disease. Supravaginal amputation of the body by abdominal section is applicable to cases of primary cancer of the body not involving the cervix: supravaginal amputation of the cervix through the vagina should be reserved for cases where the cervix to the level of the os internum is alone diseased. Total extirpation, or hysterectomy, is allowable only in cases where that operation is rendered relatively simple and safe, by the existence of complete prolapse of the uterus. There can be little doubt that all these operations are complicated and dangerous, and that in any one case it is always extremely difficult to make sure of the extent of the disease. Early amputation of the vaginal part of the cervix, by means of the galvanocautery, is likely to become a more popular method of treating cervical cancer in this country. Supravaginal amputation of the body of the uterus, the stump being secured by Koeberlé's *serre-nœud*, has proved very satisfactory in cases of fibroid, and appears to be the best manner of treating cancer confined to the body.

Case of Displacement of the Hip after Fever.

Mr. T. Pickering Pick exhibited to the Medical Society of London a boy with dislocation of the heads of both thigh-bones, the result of softening and yielding of the capsular ligaments. The right thigh-bone was dislocated forwards on to the front of the pelvis, and the left upwards and backwards on to the dorsum of the ilium. Twelve months before the boy had suffered from acute necrosis of the right tibia, probably followed by pyæmic synovitis of both hip-joints, with rapid effusion into the articulations and softening of the capsule. Owing to the position which the boy assumed, the heads of the thigh-bones pressed on this softened structure, which yielded and allowed the heads of the bones to slip out of the acetabular cavities. When admitted into hospital the right thigh was everted, rotated outwards, and flexed on the pelvis, and the left thigh was adducted and rotated inwards and also flexed, and the limbs fixed in this position. Mr. Pick performed osteotomy on both sides, dividing the neck of the femur on the right side and the shaft of the bone just below the trochanters on the left. This had the effect of bringing the limbs into a much better position, though some slight amount of inward rotation and adduction still remained on the left side. The boy could, however, walk with a certain amount of support.

Mr. Adams asked whether, in cases of dislocation after fever the capsular ligament was ruptured or distended.

Mr. Morgan related a similar case in a lad in which he had cut down and examined the condition of the parts. He found the capsular ligament distended and tense over the head of the femur; on cutting through it the latter was found perfectly healthy, but the acetabulum was almost filled with granulation tissue.

Inoculation of Tuberculosis by Circumcision.

In the *Berlin. klin. Wochensch.*, No. 35, 1886, Dr. A. Eisenberg reports a case of the inoculation of tuberculosis in a child during the operation of circumcision. It is well known that in the lower classes among the Jews, circumcision is followed by suction of the wound, either by the operator or by some other person. Syphilis has been communicated in this way in many cases, and Dr. Eisenberg's observation shows that the same may be the case with tuberculosis. The parasites at first proliferate on the surface of the wound, then reach the lymphatic glands, from which they spread throughout the organism, giving rise to lesions which sooner or later cause death. In the case referred to, the inguinal glands become swollen, and abscesses formed. Tubercle-bacilli were found in the glands, but no *post-mortem* examination was allowed. The child was born of healthy parents. Lindmann observed two similar cases in 1873, and Lehman reported ten others in 1879. In every instance, suction was performed by a phthisical operator. In all these cases the glands of the groin became inflamed within three weeks after the operation. Later on, scrofulous swellings were seen in the lower limbs, in which large

abscesses formed. In other cases, the children died of tubercular meningitis. In one case a phagedænic ulcer destroyed the glans penis. Three of the children are still alive, and have a very characteristic scrofulous aspect. With regard to these cases, however, no positive statement can be made, as the bacillus of tubercle had not been discovered at the date of the supposed inoculation, and consequently no microscopic examination was made.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. L. H. Luce publishes through D. C. Heath & Co., Boston, a partial, one-sided, prejudiced pamphlet, entitled "A Synopsis of the Nature and Effects of Alcohol and Narcotics." (8vo., pp. 28.)

——In the antiseptic treatment of summer diarrhœa, Dr. L. E. Holt regards naphthalin and the salts of salicylic acid as the most valuable antiseptics for the intestinal tract (reprint from the *N. Y. Med. Journal*).

——A valuable study is that by Dr. John J. Reese, of Philadelphia, on "Live Birth in its Medico-Legal Relations." It is printed by the Medical Jurisprudence Society of Philadelphia.

——A number of cases of poisoning from the eating of dried beef are reported in an article by Dr. R. Harvey Reed, of Mansfield, Ohio. They were apparently brought about by the presence of ptomaines.

——The subject of follicular amygdalitis is treated by Dr. A. Jacobi, of New York, in a reprint before us. It is written with his customary thoroughness of study.

——The local causes of vesical irritation in women are emphasized in a reprint by Dr. Virgil O. Hardon, of Atlanta, Ga. He very justly observes: "Many a patient has been dosed with buchu, cubebs, nitre, citrate of potash, and the like, for a supposed cystitis, when a simple examination would have revealed a fissure of the anus, a stricture of the urethra, or a displacement of the womb, as the cause of all the trouble. If the possibility of such an origin of frequent micturition be borne in mind, one will not be apt to be led into error, for the differential diagnosis will be easy."

BOOK NOTICES.

Leçons sur les Maladies du Systeme Nerveux. Par J. M. Charcot, Professeur, etc., Paris. A. Delahaye et Cie, 1887.

The name of the distinguished Professor at the Salpetriere is familiar to medical readers the world over, and the admirable lectures which are contained in this work are well calculated to increase his renown. They are well reported by different hands, and cover a great variety of topics. To illustrate their scope, we quote the titles of some of them:

"On Muscular Atrophy following Certain Articular Lesions."

"The Hysteria of Young Boys."

"Special Affection following Injury of the Sciatic Nerve."

"The Different Forms of Aphasia."

"Rhythmic Chorea and Choreiform Movements."

"The Relations of Spiritualism to Hysteria."

"Six Cases of Hysteria in Adult Males."

"Hysterical Deafness in Men."

"On the Muscular Sense and Voluntary Motion."

"On Muscular Atrophy in Hysterical Palsies."

It will be seen that such subjects as these, treated by the master alienist of the age, are eminently attractive reading. The work is illustrated by numerous wood-cuts, and is neatly printed.

A Compend of Obstetrics. By Henry G. Landis, A. M., M. D., etc. Third edition. Pp. 113. Illustrated. P. Blakiston, Son & Co., 1884.

The "Quiz-Compends," issued by the Blakistons, have proved of much utility to medical students, and are generally well prepared. The one before us by Dr. Landis, on Obstetrics, is an excellent summary, arranged in the form of question and answer, and fairly merits its popularity.

A Compend of Electricity and its Medical and Surgical Uses. By C. F. Mason, M. D., with an Introduction by C. H. May, M. D. Pp. 108. Illustrated. P. Blakiston, Son & Co., Philadelphia, 1887. Price, $1.00.

The author has aimed to present in this small volume a clear, short, and comprehensive view of medical electricity, suitable to the needs of the medical student. He may be considered to have accomplished his task in a satisfactory manner.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

POLYURIA AND DISEASES OF THE BRAIN.

In traumatic affections of the skull, the prolonged pressure of polyuria has always been looked upon as a symptom indicating the existence of some morbid condition of the brain. To determine, if possible, the exact seat of the lesion, Dr. O. Kahler (*Prager Ztsch. f. Heilkunde* vii., p. 106,) has made a series of studies.

From 25 cases of polyuria after injuries reported in literature, and from 21 of the same where the symptom accompanied diseases of the encephalon not caused by a trauma, and from two cases (one of each kind) of his own, he draws the conclusion that polyuria always indicates some affection of the parts of the brain situated in or near the posterior fossæ, the cerebellum, pons, and medulla oblongata, but that the material on hand does not permit a more exact localization.

He then experimented on numerous rabbits, and he found the same, viz., that a change in the urinary secretion results from lesions of the medulla oblongata, the pons and the cerebellum, but that the vermiform appendix has no special connection with a morbid alteration in the functions of the kidneys. Polyuria was caused most frequently when the lateral parts of the posterior end of the pons and the adjoining portions of the medulla oblongata were injured. It is a symptom showing an irritation of the cerebral parts concerned, but it is never only a functional disturbance. Polyuria, especially if not permanent, might, therefore, indicate a passing hyperæmia, or an otherwise transiently irritated state of the portions of brain-tissue mentioned, but if continuous and not amenable to treatment, the same symptom would be an evidence of some organic lesion of the same cerebral parts. This theory is confirmed by the empirical observation, that ergot is the only remedy which has thus far resulted in a cure of polyuria. This drug was first tried in a case of that kind by Prof. Da Costa, where it was successful. Since then many similar observations have been recorded in medical literature. Ergot, as well known, causes a contraction of the capillaries and, therefore, a diminished blood supply mainly in regions specially rich in capillaries, as the brain and spinal cord. A transient hyperæmia will thus be relieved, and the polyuria, when due to the latter, disappear under the influence of ergot. But when the prolonged administration of this remedy does not diminish the flow of urine, the suspicion is warranted of an organic change in the parts mentioned of the brain

being responsible for the polyuria. In such cases the symptom is of grave import, and usually predicts the fatal issue of the case. The fact that polyuria, if of long duration, occasionally ends in diabetes, sugar being added to the augmented urine, also is explained by the statements above made, for the morbid seat of polyuria in these cases is situated near to the floor of the fourth ventricle, and the morbid process might well extend to these parts, irritation of which in animals has always been followed by the appearance of sugar in the urine.

THE EFFECTS OF SEWER POISON.

The eminent Dr. W. S. Playfair, of London, recently delivered an address on defective sanitary household arrangements as a cause of puerperal disease.

It was devoted especially to the poisoning of lying-in women by sewer-gas. He justly states that this source of puerperal disease has received scarcely any attention at all, and is hardly alluded to in the text-books. But he brought forward a number of cases which can leave no doubt but that it is a frequent and serious cause of septic poisoning.

He also made the important suggestion that these poisons may be absorbed and remain latent in the system, and only show their malific influence after delivery. Instances of this kind were adduced, which must challenge the careful attention of all obstetricians.

The common use of stationary wash-stands, of bath-rooms and water-closets in the centre of the house, of a congeries of pipes connected with a foul well or common sewer—all these so-called "modern conveniences" are a standing menace to the health and life of women in parturition.

Doubtless the health of households would be better if all such were banished from the dwelling, and that, like our ancestors, we removed such necessities from our residences to the grounds adjacent.

NOTES AND COMMENTS.

Catalepsy in a Mother and Child.

Dr. Van Schoot discusses in a Dutch medical journal a case of convulsive seizures of a peculiar kind in a woman in the seventh month of pregnancy. When he first saw her she was motionless, her face being cyanotic, but her temperature, respiration, and pulse normal. She was quite unconscious, and the slightly dilated pupils did not react to light. The arms were flexed at right angles, requiring some force to move the forearms. By means of chloroform all the contracted muscles relaxed, and some hours' sleep was obtained. Afterwards she remembered nothing of the fit, but she stated that all movements of the fœtus seeemed to have ceased, and no heart sounds could be detected. These attacks were repeated frequently for a fortnight, the urine being quite normal all the time. Large doses of bromide were given without effect, but some amelioration was produced by sulphate of atropine. Latterly the attacks were associated with considerable movements of the abdominal muscles. Some temporary benefit was obtained by subcutaneous injections of pilocarpine. At the conclusion of a fortnight from the first attack labor came on, a female child being born alive, which, however, died in a week's time, after repeated convulsions similar to those affecting the mother. The mother had no attack till the fifth day (the same day that the child's first attack occurred). After this there was only one more attack two days later, complete recovery ultimately taking place. The author, referring to the diagnosis, is disposed to exclude eclampsia, because, although there were clonic contractions of the abdominal muscles, the main spasm—indeed, at first the only kind of spasm—was tonic. The entire absence of albuminuria, too, tends to exclude eclampsia. Again, epilepsy may be excluded, as after the tonic no clonic spasms occurred, and as the limbs remained fixed in a certain position for one or two hours. He therefore considers that the attacks were of a cataleptic nature, both in the mother and child.

The Use and Abuse of Pessaries.

Dr. Fitzgerald read a paper on the use and abuse of pessaries before an English medical society, in which he said it was a matter of common sense that when a body, be it uterus, humerus, or intestine, was dislocated, it should be restored to its place as soon as possible. The case was, of course, different when an organ, such as the uterus, was bound down by inflammatory adhesions, and grave consequences had followed forcible attempts at replacement, and the routine use of pessaries in such cases. The normal position of the uterus was more or less one of anteversion; he was disposed to consider congenital retroflexion, or even retroversion,

extremely rare. In cases of acute flexion, pessaries were not, as a rule, of much service. The causes which tended to push the uterus backward in women were very numerous. He considered it a mistake to keep women so long on their back after child-birth, as the heavy uterus was thereby allowed constantly to gravitate back into the hollow of the sacrum. The patient should be advised to sit up occasionally, and to lie alternately on her side and chest. He differed from those who regarded stenosis of the cervix as of no importance in producing dysmenorrhœa, for although this condition might not matter as long as the flow was fluid, yet it produced almost complete stoppage as soon as clots were formed, and uterine spasm or colic was the consequence. Dr. Fitzgerald then related several cases illustrating the relief often given by the replacement of a dislocated uterus.

Artificial Alimentation.

Dr. D. G. Hays, in an article on this subject in the *N. Y. Med. Jour.*, arrives at the following conclusions:

1. Many pathological processes arise from an improper dietary, and many others may be controlled by a proper dietary. There is a celebrated proposition by M. Broussais: "He who does not know how to manage the stomach will never know how to treat disease."

2. Mal-assimilation is a cause of disease. Peptones in the general circulation being poisons, when from any cause metabolism is interrupted, the system is prone to take on pathological conditions.

3. In pyrexia: *a.* The digestive juices, being less in quantity and impaired in quality, should be re-enforced by the artificial digestive ferments. *b.* The stomach is feeble in a muscular sense, and incapable of dealing with large quantities. Hence concentrated or predigested foods should be furnished it. *c.* The process is one of tissue destruction (histolytic). Hence we must furnish the materials for repair (histolysis). How and when to furnish these is still a disputed question. *d.* Feeding is not the cause of pyrexia, nor starvation its cure. Though the former augments it and the latter decreases it, we gain most by keeping up nutrition. *e.* The excess of urea excreted is not proof of nitrogenous waste in the blood.

An Experimental Research upon Rabies.

At the stated meeting of the Philadelphia Academy of Surgery, February 7, 1887, Dr. H. C. Ernst, of Boston, Mass., read an interesting paper on this subject, which embraced the following conclusions:

1. That there exists in the cords and brains of animals inoculated in Pasteur's laboratory a *specific virus* capable of the production of similar symptoms through a long series of animals.

2. That these symptoms are produced with absolute certainty when the method of inoculation is by trephining the skull and injection under the dura mater; with less certainty when the inoculation is by subcutaneous injection.

3. That the strength of this virus is lessened when the cords containing it are removed from the animals, and placed in a dry atmosphere at an even temperature.

4. That the symptoms produced by the inoculation of this virus only appear at a certain period of incubation, distinctly shorter when the inoculation has been done by trephining than when done by subcutaneous injection.

5. That injections of the virus modified in strength by drying, and in the manner prescribed by Pasteur, exert a very marked protective influence against an inoculation with virus of full strength.

6. That a very moderate degree of heat destroys the power of the virus entirely, whilst prolonged freezing does not injure it.

Right Hemianæsthesia of Cerebral Origin: Trephining.

The *Brit. Med. Jour.* of March 5 says:

A case of much interest is at present under the care of Professor Grainger Stewart in the Edinburgh Royal Infirmary. The patient, an elderly man, received an injury to the back of his head on the 1st of January last. The accident was not immediately followed by serious symptoms. Since then, however, he has complained of gradully advancing anæsthesia of the right side, especially of the arm and leg. On admission, the anæsthesia was precisely determined, and he was found to be suffering from double optic neuritis. During the last few days, signs of an advancing condition of torpor manifested themselves. Accompanying this, there was evidence of motor paralysis in the anæsthetic limbs. The temperature was subnormal. Professor Grainger Stewart concluded that the symptoms were due to pressure, either cortical or the result of cerebral abscess; and, as the symptoms were progressive, he requested Professor Annandale to operate. Accordingly, on February 22, Mr. Annandale trephined the frontal bone, immediately

in front of the left anterior parietal angle. About two ounces of a dark-colored, grumous fluid escaped, and it was found that the finger could be passed freely beneath the dura mater into a large cavity, which separated the surface of the brain from the dural covering. The surface of the brain appeared healthy. The cavity was gently syringed, and the patient, so far, is doing well.

Death from Whitlow.

Dr. R. H. A. Hunter thus writes to the *Brit. Med. Jour.:*

W. P., aged 7, was brought to my consulting-room on the evening of October 6, 1886, suffering from a small whitlow on the ring-finger of his left hand. On examination, I found the whole left hand and forearm œdematous, and inflamed in patches. The temperature was 101°, the pulse 120, and the tongue was thickly coated. Having made an incision on either side of the distal phalanx down to the bone, and ordered linseed poultices with frequent warm water bathing, I prescribed a calomel and compound jalap powder, with a saline mixture containing small doses of aconite. On the 9th, the temperature and pulse became normal. The patient was then put upon quinine, steel, and port wine. On the 10th, the œdema of the hand and arm had disappeared, and the finger looked comparatively healthy. On the 11th, retching and vomiting set in, without any increase of either pulse or temperature, and continued unabated in spite of the use of such remedies as bismuth, cerium, hydrocyanic acid, opium, etc., until the morning of the 12th, when death took place from exhaustion, although beef-tea and port wine were frequently administered by enema. From first to last there was neither swelling nor tenderness of any part of the abdomen, and head-symptoms were entirely absent, the child being conscious to the last.

Arm and Shoulder Presentation; "Spontaneous Expulsion" (Douglas).

Dr. Penruddocke (*Brit. Med. Jour.*) was called, on December 12th, at 1 p. m., to see a Mrs. W., who was in labor with her second child. On arrival, he found the right arm of the fœtus already in the world, with the right shoulder firmly fixed against the arch of the pubes, and was informed by the nurse that it had been in this position for the last two hours, the liquor amnii having been discharged at 10 a. m. The pains had been regular and severe, but were becoming weaker; he therefore decided to turn, but found great difficulty in introducing his hand, the fœtus being so firmly fixed and low in the pelvis. He had nearly succeeded in reaching a foot, when the uterus commenced acting very forcibly, compelling him to withdraw his hand.

The pains continued, and the shoulder still remaining fixed beneath the pubes; the spine and body of the fœtus became flexed upon itself; the nates descended and swept over the perineum, being followed by the lower extremities. The other arm now came down, and the head was delivered as in cases of breech presentation. The child, a girl, appeared to have been dead some hours; it was quite mature, but thin, and the funis was twisted twice round its neck. The placenta followed immediately, and when he left the house, his patient was feeling very comfortable.

Inherited Phthisis.

Professor Firket (*Revue de Méd.*, January, 1887), writing upon the subject of heredity in tuberculosis, points out certain difficulties in the acceptance of the doctrine of direct transmission from parent to offspring. Such transmission may conceivably take place before conception, the tubercular bacilli being associated with the sperm or germ—a purely hypothetical idea—or through the medium of the placenta, and therefore solely by the maternal blood. He contends that there is not such positive proof of infection of the maternal blood, and thereby of transmission of disease to the fœtus in the case of tuberculosis, as there is in anthrax, or syphilis, or variola and other affections. Moreover, he shows that in ordinary phthisis fully one-half of the cases do not exhibit, in the presence of remote secondary lesions, evidence of blood infection. It is for the most part a local disease of the lung, and such secondary lesions as do occur may be explained in many cases apart from general blood contamination. How different, it may be said, from the old notion of phthisis! But the fact of the lung being the primary seat of tubercular disease in inherited cases (says the *Lancet*) is almost conclusive against the congenital theory; for if the fœtus were infected through the blood, the chances are that the lungs would not suffer more than any other organ.

The Cure of Boils by Injections.

Dr. Bidder described, at a recent meeting of the Berlin Medical Society, a new method

of treating furuncles by parenchymatous injections of carbolic acid. If the boil is a small one, he gives one injection of a few drops of a solution of carbolic acid (2 per cent.); if it is of medium size, two injections are given, the half or the whole of a Pravaz-syringeful of the solution being used on each occasion. In the case of large furuncles, for example, half the size of a man's hand, Dr. Bidder injects at four different spots the contents of four Pravaz syringes half or wholly filled with a solution of 2 per cent. of carbolic acid. These injections are given only once. This treatment is strikingly successful. There is some smarting at the seat of injection at first, but the pain soon disappears, and the next day there is a marked improvement in the patient's condition. The inflammatory swelling subsides very quickly, and in eight or ten days even the largest furuncle is dispersed. By this plan no unsightly scars are left, a circumstance which in many cases is of considerable importance. The success of the treatment is probably to be accounted for by the fact that either the microbes which cause the disease are killed, or the medium in which they flourish is destroyed.

Penetrating Abdominal Wound.

At a meeting of the Lucerne Medical Society, Drs. Steigers (senior and junior) showed a man who, in a brawl, had been stabbed in the hepatic region with a jack-knife. From the wound, which measured eight centimetres in length, there protruded four intestinal loops about eight or ten feet long, and perforated in seven places. Having sewn up the holes, the authors enlarged the abdominal wound, and returned the bowels through it, closing it afterwards with an *étage* suture. The operation lasted two and a half hours, and was performed under the internal administration of tincture of opium (140 minims), chloroform being contra-indicated by the extreme prostration of the patient. The temperature never rose above 38.2° C. For the first four days the patient was allowed neither food nor drink; on the fifth day, 150 grammes of water and the yolk of two eggs were given. The bowels were opened with an enema on the eighth day, and, on the tenth day the patient was allowed to get up.

Physical and Chemical Properties of Antipyrin.

Professor V. A. Tikhomïroff, of Moscow, says (*Proceedings of the Moscow Physico-Medical Society*, Nos. 5 and 6, 1886,) that a pure preparation of antipyrin is rapidly and completely dissolved in water, the solution having a neutral reaction. The most characteristic reaction of the drug is that a very weak, slightly yellowish, solution of perchloride of iron becomes dark reddish-brown in color when a small quantity of antipyrin is added to it. On the subsequent addition of a drop of sulphuric acid, the mixture becomes completely discolored. Another characteristic property of the drug is that, on mixing a watery solution of it with an excess of nitrous acid (or, rather, with a mixture of KNO_2 and HCl), a green precipitate, bearing the name of "iso-nitroso-antipyrin," appears, and forms spherical masses, which, as seen under the microscope, closely resemble colonies of yeast-fungi (*saccharo-myces eerevisiæ*). This appearance is produced by the aggregation of extremely minute crystals, having a double refraction. The precipitate is soluble in caustic alkalies and ammonia, the solution being of a greenish-yellow color.

Extirpation of the Spleen.

At the recent congress of Russian medical practitioners, Dr. A. G. Podrez, privat-docent in Kharkoff, read a paper on extirpation of spleen, including the notes of a case in which he himself had recently performed this operation. The patient was a woman with ague-cake, associated with ascites and extreme cachexia. The operation was performed on the 22d of November last; the patient subsequently went on well, being able to get up on December 10. The weight increased and the ascites disappeared. On the 16th, however, she had a rigor, and the urine contained a large quantity of albumen and hyaline casts. Death occurred on the 27th, and was due, as shown by the necropsy, to diffuse parenchymatous nephritis. The total number of cases of extirpation of the spleen collected by Dr. Podrez (including his own) is forty-two. Of these one was performed in 1549 by Saccharelli, and one in 1711. The rest all belong to the present century. If his own case is reckoned as a recovery, the mortality is 73 per cent.; if otherwise, the mortality is 76.

Endoscopy of the Male Bladder.

Dr. Nitze recently exhibited his electric apparatus for the examination of the male bladder to the members of the Berlin Medical Society. This endoscope is not altogether new, but it has lately been so much improved that a short account of it may not be out of

place. Endoscopic exploration is often useful in leading to the discovery of small stones or tumors, and in revealing the cause of the bleeding in certain obscure cases of hæmaturia. Sir H. Thompson's perineal incision does not always allow of a satisfactory examination being made with the finger, while Guyon's "high operation" is dangerous, as compared with the mere introduction of a tube by the natural passage. Dr. von Bergmann related a case of vesical tumor on which he had operated after examination with Nitze's "cystoscope," and dwelt on the advantage, in a procedure of such gravity as opening the bladder, of being perfectly acquainted with the exact site and size of the tumor.

Tracheotomy in Diphtheria.

After discussing the time at which this operation should be resorted to, in the *Brit. Med. Jour.*, March 5, Dr. W. Watson Cheyne thus concludes: "It will be evident that the object of this paper is not to recommend the application of any particular antiseptic substance in this disease, but to raise the question of the indications for performing tracheotomy in diphtheria. And I believe more lives will be saved by opening the trachea early, as soon as the larynx is evidently attacked, and by attempting to prevent the spread of the membrane downwards than by delaying the operation till symptoms of obstruction are marked. The probable advantages, I think, more than counterbalance the possible dangers, for, apart from the advantages generally admitted to attend early tracheotomy, there is the further advantage that there is a possibility of arresting the spread of the disease, and also of applying medicaments to the larynx."

Multiple Neuritis after Diphtheria.

Dr. Campbell Pope presents notes of a case under this title in the *Brit. Med. Jour.* A young man was admitted into the Queen's Hospital, Birmingham, three months ago, with almost complete paralysis, which had commenced in the legs, and later on had affected the forearms. Ten weeks previously he had had a sore throat. His sister, living in the same house died of diphtheria, and his larynx was anæsthetic on admission. There were well marked dropping of the hands and feet, emaciation, marked tenderness in the calf muscles and along the nerve trunks. He suffered from shooting pains before admission. A prick of a pin caused two sensations, touch being first perceived, and pain after. The reaction of degeneration was present in the extensor muscles of the legs and forearms. He was now improving gradually, taking 40 minims of the liquor strychniæ three times daily, and being galvanized and rubbed.

The Curability of Cancer by Operation.

In a paper on this subject published in the *Medical Record*, Dr. George F. Shrady arrives at the following conclusions:

1. Cancer is essentially a local disease, and can be cured by operation in spite of recurrence.

2. Operation, when it does not cure, prolongs life and diminishes the total amount of suffering.

3. Operations should be repeated as often as there is any chance of entirely removing recurrent growths.

4. The earlier and the more thoroughly the operation is performed the better.

5. The disease, when it recurs, is generally of a milder type than that of the original growth, less painful and less exhausting.

6. Antiseptic surgery makes more radical operations possible, with better ultimate results than formerly obtained.

Antiseptic Collodion.

The *Journal de Médecine* of December 26 contains an account of a new kind of "collodion," which is antiseptic and promotes cicatrization. It does not cause inflammation, and may be substituted for collodion made from gun-cotton, in the treatment of wounds and bruises. Like traumaticine, it is efficacious in relieving neuralgic pains, and acute or chronic rheumatism. The affected parts should be sponged with it every twenty-four hours, and in serious cases every six hours. If strips of linen or silk be soaked in this collodion, an excellent sticking plaster is obtained, which quite equals English court-plaster. The following is the formula: Mastic in globules, 3 grammes; balsam of Peru, 1 gramme; narcotine, 1 gramme. Each ingredient should be ground separately, and 5 grammes of chloroform added thereto.

Gunshot Wound of Vertebræ.

Before an English Medical Society, Mr. J. T. J. Morrison showed a man, aged 25, who nine weeks ago shot himself in the mouth, discharging a No. 7 conical Eley bullet from an ordinary revolver. On admission there was some shock, but no loss

of consciousness. The tongue and palate were blackened with powder; the soft palate presented a round perforation, through which the tip of the finger could feel an opening in the bony wall of the pharynx. A probe passed through this aperture, traversed a canal in the bone about an inch in length, and impinged on a hard substance at the bottom. There were no signs of spinal concussion or hemorrhage. No attempt was made to extract the bullet. The patient was now in excellent health, the hole in the vertebral column having closed, and its place being indicated only by a slight elevation.

An Example of Abortive Treatment.

Dr. C. R. Illingsworth thus concludes a paper in the *Med. Press:*

"To give examples of abortive treatment by germicidal remedies, I might mention that of scarlet fever and diphtheria, where, by the administration of the biniodide of mercury every two hours, in solution of potassic iodide, those germs which have found an entrance to the circulation, and whose presence there is indicated by the scarlatinal rash and enlarged cervical and submaxillary glands, are rapidly followed and destroyed, with the grand result of rapid restoration to health, and the prevention of those fearful sequelæ to which multitudes have fallen victims."

Tuberculosis of Pharynx.

To the Medical Society of London, Mr. Lennox Browne showed a young woman, aged 20, married, and the mother of three children, who was the subject of tuberculosis of the fauces and pharynx, extending to the posterior wall of the larynx, and slightly involving the right arytenoid cartilage. The lung showed only incipient phthisis, but tubercle bacilli were plentiful at the seat of ulceration. The patient had been unable to swallow, but the dysphagia was cured by scraping the diseased surface, previously anæsthetized by cocaine, and then applying the solutions of lactic acid (20, 40, and 60 per cent.) to it daily for three weeks. This plan had been recommended by Krause, of Berlin.

Antifebrin in the Royal Infirmary, Edinburgh.

Antifebrin has now been used for several months in the Royal Infirmary, Edinburgh. It was introduced by Professor Grainger Stewart shortly after the first account of its properties was published, and since then it has been used largely in more than one ward. The antipyretic qualtities of the acetanilide have been most thoroughly tested, and it now occupies a high place among the febrifuge resources of the Infirmary. More especially it has been proved superior to antipyrin, kairin, and thallin, in its freedom from accompanying disadvantages, such as the production of vomiting, rigors, and other discomfort, at the various stages of its action.

Trephining for Supposed Abscess of Brain.

Mr. James Black relates in the *Brit. Med. Jour.* the case of a young man who had had symptoms pointing to abscess connected with disease of the ear. Puncture of the mastoid cells having failed to relieve him, the skull was trephined one inch and a quarter above and behind the external auditory meatus, and the brain explored for the abscess. The wound was subsequently reopened, and further search made with a trocar and canula, but with no better result. In spite of severe constitutional symptoms, the wound healed well with the exception of a small sinus, and the patient ultimately made a good recovery.

Chronic Cocaine Poisoning.

Dr. Buebler, of Lucerne, describes (*Brit. Med. Jour.*) two cases of chronic cocaine poisoning. The patients were a man and his wife, who had formerly been morphinists, and who took to cocaine by way of antidote. They gradually reached a daily hypodermic dose of the latter equal to 2 or 2.5 grammes. The prominent symptoms were incoherence of ideas and optical delusions. They saw everywhere (on their hands, beds, walls, etc.,) small spots, worms, and the like, presenting incessant movements and changes in form. Absolute discontinuance of the drug was followed by complete recovery.

Calculus as the Cause of Perityphlitis.

A Swedish surgeon, Dr. Sigurd Lovén, has published the notes of a case of perityphlitis, followed by a tumor in the ileocæcal region, and abscesses opening over the coccyx through the abdominal walls and rectal walls. Ultimately a calculus was passed through the abdominal wound, weighing 79 centigrammes, and measuring 2.5 centimetres by 1.3 centimetres. It was composed of alkaline phosphate of lime. Dr. Lovén believes this had existed for a considerable period, and that its situation had been in the vermiform appendix.

A Pleasant Vehicle for Cod-Liver Oil.

The following formula, as given by "Heder" in the *Chemist and Druggist*, is said to give a delicious emulsion:

Yolks of two eggs.	
Powdered sugar,	4 ounces.
Oil of bitter almonds,	2 drops.
Orange flower water,	2 ounces.

Mix carefully, and add to this gradually an equal bulk of cod-liver oil.

A Hint in Dilatation of the Œsophagus.

In dilating strictures in the upper portion of the œsophagus, Dr. J. Solis-Cohen finds the passage of instruments much facilitated by forcibly drawing the larynx and trachea forward between the thumb and fingers of the disengaged hand, at the moment that the obstruction is reached by the dilating instrument.

"Rough on Rats."

It may be well to bear in mind, says Professor Bartholow, that the popular poison "Rough on Rats" owes its efficacy to phosphorus. Being an oily or fatty preparation, when taken into the stomach its action as a poison is very rapid.

News and Miscellany.

American Medical Association.

The thirty-eighth annual session will be held in Chicago, Ill., on Tuesday, Wednesday, Thursday, and Friday, June 7, 8, 9, and 10, commencing on Tuesday, at 11 a. m.

"The delegates shall receive their appointment from permanently organized State medical societies, and such county and district medical societies *as are recognized by representation in their respective State societies*, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States.

"Each State, county, and district medical society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number: *Provided*, however, that the number of delegates for any particular State, territory, county, city, or town, shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association."

Secretaries of medical societies are requested to forward, *at once*, lists of their delegates.

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secretaries *are, by special resolution*, requested to send to him, annually, a corrected list of the membership of their respective societies.

SECTIONS.

"The chairmen of the several sections shall prepare and read, in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective sections. * * * *."—*By-Laws*, Art. II., Sec. 4.

Practice of Medicine, Materia Medica, and Physiology.—Dr. J. S. Lynch, Baltimore, Md., Chairman; Dr. J. B. Marvin, Louisville, Ky., Secretary.

Obstetrics and Diseases of Women and Children.—Dr. F. M. Johnson, Kansas City, Iowa, Chairman; Dr. W. W. Jaggard, Chicago, Ill., Secretary.

Surgery and Anatomy.—Dr. H. H. Mudd, St. Louis, Mo., Chairman; Dr. A. M. Pollock, Pittsburgh, Pa., Secretary.

State Medicine.—Dr. Geo. H. Rohe, Baltimore, Md., Chairman; Dr. Walter Wyman, U. S. Marine Hospital, New York, Secretary.

Ophthalmology, Otology, and Laryngology.—Dr. X. C. Scott, Cleveland, Ohio, Chairman; Dr. J. H. Thompson, Kansas City, Mo., Secretary.

Diseases of Children.—Dr. DeLaskie Miller, Chicago, Ill., Chairman; Dr. W. B. Lawrence, Batesville, Ark., Secretary.

Oral and Dental Surgery.—Dr. John S. Marshall, Chicago, Ill., Chairman; Dr. A. E. Baldwin, Chicago, Ill., Secretary.

Medical Jurisprudence.—Dr. I. N. Quimby, Jersey City, N. J., Chairman; Dr. H. H. Kimball, Minneapolis, Minn., Secretary.

A member desiring to read a paper before a Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the Chairman of the Committee of Arrangements at least one month before the meeting.—*By-Laws.*

Committee of Arrangements.—Dr. Charles Gilman Smith, Chicago, Ill., Chairman.

Amendment to By-Laws.—Create a new Section, to be known as the Section on Dermatology and Venereal Diseases.

As it is required to issue the programme at least one month before the session of this body, all who desire to read papers at the session to be held at Bedford, June 29, should *at once* forward the title and a brief abstract

of the same to W. S. H. Gump, Chairman Committee of Arrangements.

WM. B. ATKINSON,
Permanent Secretary.

A Colony of Lepers.

The Hawaiian letter in *Boston Bulletin* says:

"Touching at Molokai we were afforded an opportunity for inspecting the leper colony established there. Many of these unfortunates were found to be in the last stages of the disease. The sight of these poor creatures would serve to excite the curiosity of only the most morbid nature. Their cheerfulness, even when rendered incapable of locomotion by the ravages of the disease, is somewhat remarkable, while their number include many Europeans, the Chinese being by far in excess of all other nations.

"The disease is said to be rather constituent in character than the result of cutaneous inoculation, as might be erroneously supposed. Science, however, has not been enabled to do much toward relieving the sufferings of these people, although their wants appeared to be generously provided for through the liberality of the government and that of foreign residents. The disease is contagious, while the hopeless misery of many of its victims in Hawaii would justly excite the pity of any beholder. One feature of the disease is the fact that there are many persons now living at Molokai who for years prior to their arrival there as patients had been living in various parts of the kingdom in utter ignorance of the appalling fact that leprosy was insidiously attacking the system.

"One instance in point was that of an aged Catholic priest, who discovered his deplorable condition only after an accidental breaking of a lighted lamp. It followed in his case that while removing some of the hot fragments in his effort to prevent any further damage, he found that he had lost the sense of feeling in his right hand. Instantly divining that he was afflicted with the dread malady, he heroically sought refuge among others at the leper settlement on Molokai, where I believe he died several years since."

Scenes and Lessons of the Earthquake.

The *Brit. Med. Jour.* says:

The graphic accounts which refugees from the Riviera have brought to London of the scenes at Nice and Monte Carlo during the earthquake gave a vivid impression of the gruesome terror of the situation, and the tendency which all such panics have to bring out the brute element in man. *Sauve qui peut* was the prevailing sentiment; and "the devil take the hindmost" was only in too many cases the corollary which the impulse of panic added. The scenes to be witnessed were made up pretty equally of the painful, the disgusting, and the ludicrous. Such a stampede of respectable and distinguished half-naked fugitives of all ranks has not been witnessed in our time. Fear and a selfish impulse of self-preservation appear in too many instances to have been the ruling sentiments; but happily also some of the higher traits of character were shown, and amidst stories of the most brutal selfishness and unreasoning panic it is a relief to hear of a few Englishmen who spent their whole time in calming the fears, aiding the immediate necessities, and relieving the distresses of the women and children. It is painful to be told that the first train from Monte Carlo was wholly filled with men, carrying only one lady, and for her a seat was secured only by her husband, who knocked down some forcibly intruding claimants and defended by main force the seat which he secured for his wife. The invalids appear to have suffered much from the cold, and in some phthisical cases hæmoptysis occurred. The sad story of after-suffering remains to be told; meantime, the visitors have reason for congratulation that they have emerged from so terrible a situation with so little injury. It will be long before the Riviera will altogether recover from the shock to confidence which this disaster has given. In the reconstruction which must necessarily follow, it is to be hoped that scientific attention will be given to the system of drainage. In many places, it is stated, the drains and water-supplies will need to be partially reconstructed, and it is to be hoped that a better system will be adopted than that which at present exists.

A Physician's Disappearance.

A dispatch from Clifton Springs, N. Y., March 12, says:

"Dr. James McGammon, one of the physicians at Dr. Henry Foster's Sanitarium here, has disappeared in a very unaccountable way. He took a train for Rochester to see a sick friend, but inquiries show that the friend was not sick, nor had he seen the doctor. Dr. Gault, chief physician at the Sanitarium, received a letter from him last Sunday stating that he was then down the bay on his way to Europe, and that he would

write his wife immediately on his arrival in London. Inquiries in New York show that Dr. McGammon's name was not on the register of any outgoing steamer.

"The doctor was young, of unquestioned truthfulness and integrity, cheerful, bright, kind, sympathetic, and beloved by the faculty, help, patients, and villagers. He was a leading member of the Young Men's Christian Association, and never drank a drop of liquor in his life. It is believed that he has been suddenly stricken with insanity."

Cholera in South America.

The *Press* editorially says that cholera at the last advices from South America was waning, and it is to be hoped that our comparatively limited commerce with the Eastern coast of the continent is not to be hampered by quarantine precautions unless they absolutely necessary. The disease appeared last autumn on the west coast of South America, and Chili quarantined against it, the California State Board of Health also considering precautions necessary. It has not traveled far to the North, but taking, as might be expected, a course the reverse of that which it follows in the Northern Hemisphere, passed southward, and in spite of the precautions of Chili has followed the currents of trade across the South American continent. Mendoza and Tucuman, in the interior of the Argentine Confederation, have suffered severely, but the quarantine of the States has checked its progress, and at points like San Luis, midway between Chili and Buenos Ayres, its ravages have been few. Business at Buenos Ayres has revived as the fears of an attack have lessened and unusual prosperity has attended the opening of the year.

A Young Epicure.

A Boston lady, whose sister lives in Georgia, and whose mansion there is overrun, like every other big Southern residence, with black servants, receives frequently from her odd stories of these always funny people. Her stout colored cook, a charmingly loquacious person, has two small boys, who serve as errand bearers and personal servants to the lady of the house. One of these boys, whose name is Ivy, has a devouring passion for molasses, and not only decorates his countenance with it on all possible occasions, but cannot possibly eat his food without it. One day lately Ivy was served with some bread and honey at his lunch in the kitchen, and promptly called for molasses. "Land sakes!" said his mother; "fo' to put on de bread 'n' honey?" "Sartin', mammy." "Lan' ob de livin! ef dat boy Ivy had de Angel Gabr'el sarved up on de table, he's ask right off fo' de 'lasses to put on him!"

The International Medical Congress.

J. J. Chisolm, M. D., of Baltimore, Md., has been appointed President of the Section of Ophthalmology of the Ninth International Medical Congress, in the place of Dr. E. Williams, who was compelled to resign on account of ill health. Judson B. Andrews, M. D., Superintendent of the Hospital for the Insane, Buffalo, N. Y., has been appointed to the office of President of the Section of Psychological Medicine and Nervous Diseases, made vacant by the recent death of Dr. John P. Gray. These are excellent appointments, both parties being widely known and eminently well qualified for the respective positions assigned to them. No vacancies now remain in the list of chief officers of the preliminary organization of the Congress or of its Sections; and our information from all departments is of the most encouraging character.

Detection of Blood-Spots on Iron.

Dr. Dannenberg contributes some valuable data on detection of blood-spots on iron. Blood is easily proven on ordinary surfaces by means of the crystal of haemine, but when blood-spots on rusty iron are to be examined their detection is not so simple a matter, as the iron-rust seems to form a combination with it. Dr. Dannenberg, however, states that if a few drops of a 10 per cent. solution of caustic potash be placed on the spot, and thus loosened, the rust scraped off and treated with ammonium sulphide and water, and then handled according to the usual method, elegant extended rhombic crystals will be formed. He considers these as conclusive proof, and names them "Haemidin" crystals.

Official Representatives to the Ninth International Medical Congress.

It was announced several weeks since that Dr. Leopold Servais, of Antwerp, had been appointed by the Belgian Government as representative to the Congress at Washington. More recently we learn that Deputy Surgeon-General Jeffrey A. Marsten, M. D., of the British Army, has been designated a representative by his Government, and the Government of France, through the Acad-

emy of Medicine, has designated as representatives Drs. Charpentier, Dujardin-Beaumetz, Léon Le Fort, Trélat, and Vallin. From all directions, at home and abroad, the indications of a very large and interesting Congress are of the most gratifying character.

The Ear as a Criterion of Character.

According to the *Boston Medical and Surgical Journal*, the ear affords a better criterion in estimating human character than any of the other features. An ear without well defined elevations and depressions indicates selfishness and want of delicacy of perception; the possessor of a thick, well-shaped, highly-tinted ear, set well forward, is usually ungrateful, grasping, and lacking in depth of feelings; a thin ear indicates keen susceptibilities; a projecting ear, alertness; a broad ear is more coarsely practical. The perfect ear lies close to the head, is gracefully rounded with pretty curves, strong lines, and firm, delicately tinted cartilage.

A Simple Test for Butter.

There is a qualitative test for butter so simple that any housewife can put it into successful practice (*Scientific American*). A clean piece of white paper is smeared with a little of the suspected butter. The paper is then rolled up and set on fire. If the butter is pure, the smell of the burning paper is rather pleasant, but the odor is distinctly tallowy if the butter is made up wholly or in part of animal fat.

The International Medical Congress.

The item appropriating $50,000 for the Congress was placed in the Sundry Civil Appropriation Bill, and was therefore, we presume, passed. If so, this sum will be a great help in promoting the success of the Congress. Several steamship lines have reduced rates to $80, $90, and $100 for the round trip across the Atlantic.

Mr. Beecher on the Act of Dying.

Mr. Beecher was once asked by one of his myriad of correspondents: "How shall I feel when I come to die?" The great preacher replied, characteristically: "You will probably feel stupid," referring to the kindly provision of nature in benumbing the faculties when putting her children to their last sleep.

Personals.

—Dr. William Goodell resigned recently the post of Physician-in-Charge of the Preston Retreat, which he has held for twenty-two years. Dr. Joseph Price was elected as his successor.

—The late Rev. Henry Ward Beecher's body was placed in a vault in Greenwood Cemetery. The services were quiet. The dead preacher's will bequeathes his estate to his family.

—Dr. William A. Hammond will open the April *Popular Science Monthly* with an article entitled "Brain Forcing in Childhood." The paper gives a picture of the evils of the book-cramming process, and contains a plea for fewer studies, more direct contact with nature, and less of the intervention of books.

—Dr. Leeds, of Lincoln, Ill., offered $5 to the Ladies' Missionary Society if twenty or more young ladies would sit together two hours without speaking. Twenty-six won the money, in spite of efforts to make them talk.

Items.

—Senor Don Dr. Rodolfo del Castillo and several other practitionors in Cordova, are forming a local Spanish society of Hygiene.

—"Physician, heal thyself," jocularly said a rich man to the doctor as he came into his office. "Thanks; that is what I propose to do," replied the doctor, presenting a bill for $200. He went out well heeled.

—M. Courbarien, intern of the maternity department of La Charité, Paris, died recently from typhoid fever at the early age of twenty-eight years. He was a man of much promise, and was highly esteemed, as evidenced by the testimony given by Dr. Budin, in his speech on the occasion of the funeral.

—Mr. J. S. Morgan, the well-known American banker in London, has promised the munificent sum of $50,000 in aid of the funds of Guy's Hospital, on condition that the $500,000 required to put the institution into a state of thorough efficiency be secured by May 1.

—A case of myxœdema was exhibited at the Berlin Medical Society by Professor Senator on February 9. He remarked that this was only the second case observed in Berlin, the other having been reported by Dr. Riess at the end of last year. Together with two cases described by Professor Erb, of Heidelberg, this case made the fourth reported in Germany.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

GREEN SPRING SANITARIUM,
AND
WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten acres. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and massage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

BELLEVUE HOSPITAL MEDICAL COLLEGE,
CITY OF NEW YORK.

SESSIONS OF 1887-88.

The REGULAR SESSION begins on Wednesday, September 21, 1887, and ends about the middle of March, 1888. During this Session, in addition to the regular didactic lectures, two or three hours are daily allotted to clinical instruction. Attendance upon at least two regular courses of lectures is required for graduation.

The SPRING SESSION consists of recitations, clinical lectures and exercises, and didactic lectures on special subjects. This Session begins about the middle of March and continues until the middle of June. During this Session, daily recitations in all the departments are held by a corps of Examiners appointed by the Faculty.

The CARNEGIE LABORATORY is open during the collegiate year, for instruction in microscopical examinations of urine, practical demonstrations in medical and surgical pathology, and lessons in normal histology and pathology, including bacteriology.

For the annual Circular and Catalogue, giving requirements for graduation and other information, address Prof. AUSTIN FLINT, Secretary, Bellevue Hospital Medical College, foot of East 26th Street, New York City.

FOR SALE.

Practice and residence in a thriving town of Southeastern Pennsylvania. Property itself worth Thirty-five Hundred Dollars, and practice worth over Twenty-five Hundred per year. Buildings new and commodious. Opposition light to a good man. Advertiser sells to go to a city, and will use his influence for successor. A population of twenty-five hundred within one mile, and active works employing several hundred hands. Price for property and influence, Four Thousand Dollars. Two railroads terminate in the borough, which is located in a good farming community, good society, schools, and churches.

For particulars, address "H.,"

THE USE OF HYDROBROMIC ACID AS A REMEDIAL AGENT.

BY J. M. ANDERS, M. D., PH. D.,

Of Philadelphia.

During the past five years the writer has been well nigh daily prescribing ac. hydrobromici dil. in a variety of affections, but chiefly in complaints calling for a neural sedative, with varying, though upon the whole, gratifying success.

Though this substance was discovered as early as 1826, by Ballard, it was first employed as a medicinal agent in 1875 by Wade, of Detroit, and was investigated by experiments upon lower animals so recently as 1881, by Dr. Reichert. According to the results obtained by the latter observer, the physiological effects of this drug are quite similar to those of the bromide of potassium, though they are more transient than the latter. "It was found to depress the reflex functions of the spinal cord, but its effects upon the brain were not observed." Already prior to the date of the experiments by Reichert, clinical experience had established the fact that this agent is very useful as a substitute for the bromides of sodium, ammonium, and potassium. There are, however, certain conditions in which this acid is more beneficial, and others in which it is less so, than the bromides. It has been especially recommended to prevent the headache, tinnitus aurium, and other disorders occasionally following the use of large doses of the sulphate of quinia. Now, my own experience, as well as that of Hammond and others, develops the fact that so far from being better adapted than the bromides to obviate these unpleasant symptoms, it is really less efficacious than they.

The chief condition in which the hydrobromic acid and the bromides are about equally serviceable, or, in other words, the conditions in which it forms an excellent substitute for the bromides are, according to my own conclusions, which are based on several trials of the drug in every complaint, to be enumerated, as follows: whooping-cough, neuralgia, troublesome coughs occasioned by laryngeal or bronchial irritation, and cerebral hyperæmia. As the result of a half dozen trials of this remedy in cases of functional irregularity of the action of the heart associated with an excited state of the general nervous system, it was found to be less serviceable than the bromides of sodium and potassium, which were employed in a series of a dozen cases of the same character.

I have acted upon the suggestion by Fothergill (Med. and Surg. Reporter, vol. xxxv., p. 317), viz., to prescribe it in combination with quinia in heart troubles such as above outlined, and found it to yield truly admirable results. During the last twelve months, I have chosen from among the frequent examples of organic heart disease coming under notice, a number of those in which the valvular lesions were connected with irregular cardiac contractions, and have exhibited to them this drug in combination with digitalis, arsenic, and iron, with really striking results. Under these conditions the drug appears to exert a tonic effect upon the cardiac muscle, and to bring about more regular contractions. As a substitute for the bromides, this acid may

also be recommended in ovarian excitement and vesical irritation, when the latter is not due to excessive acidity of the urine. In a series of six cases of ovarian sensitiveness occurring in hysterical young females, two were promptly relieved by it, the remaining four only partially. My notes furnish the details of a case which appeared in a lady nearing the change of life.

Frequent desire to micturate was the most distressing symptom; urine contained no pus. An uterine examination revealed only a somewhat congested condition of the pelvic organs. She was practically cured within a fortnight by ac. hydrobromic dil. in doses of half a drachm given four times daily, and this after the bromides had failed of relieving her. From my experience with the drug in this and other cases of the same sort, I am inclined to believe that this acid is especially adapted to the treatment of excitability of the bladder or ovaries where associated with decided vascular congestion of these organs. Among the affections in whose treatment this drug possesses virtues surpassing those of its alkaline salts, are to be particularly mentioned, neurasthenia and post-hemiplegic spastic contractions of certain groups of muscles.

In two cases of neurasthenia of the sort so ably described by Prof. H. C. Wood (*Pepper's System of Medicine*, vol. v., page 354), excited, in one instance, by prolonged and strenuous application to business pursuits, and neither preceded by nor associated with any other discoverable disease; in the other excited by the presence of bleeding piles, lasting eight years, which latter condition is now rarely manifested. Both suffered at first from attacks of vertigo connected with temporary cerebral hyperæmia followed by apparent destruction of muscular strength. One of these subjects became, for a time, disinclined to maintain his reputation as an active business man; the other exhibited marked vaso-motor disturbances. But enough of the symptoms present have been related to show that both cases were typical instances of neurasthenia. For both patients, I had prescribed alternately the bromides of sodium and potassium, and also a pill composed of iron, quinia, and arsenic. As a result of this treatment, the attacks of vertigo became somewhat less frequent and less severe; but there was observed soon to be an increased prostration of nervous and muscular strength.

While reflecting upon my apparent dilemma, it occurred to me to replace the bromides with hydrobromic acid, which was done. The acid was found to be endowed with all of the favorable influences of the bromides, and not with any of their weakening effects upon the muscular system, which now seemed to improve in strength, an effect that was greatly to be desired. This plan was continued for two months, and at the end of this time a practical cure was obtained. It should be noted that an essential part of the treatment consisted in lessening the daily working hours and enjoining moderate exercise in the open air.

My experience with this drug in spastic contractions of certain groups of muscles in post-hemiplegia is limited to a single case. The patient, a male, aged 68 years, first applied to me in July, 1886, giving the following previous history: From his boyhood days up to the summer of 1884, he had always enjoyed good health; at that period, or two days before the date of his first visit, he had an attack of apoplexy, causing almost complete paralysis of the right side of the body. About six months later, after having sufficiently recovered to be enabled to walk without difficutly, he began to be seized with convulsive movements of the affected arm, the contractions commencing in the flexor muscles of the thumb, extending up the arm to the shoulder, and usually affecting the pectoral muscles of the same side. His attacks increased in violence, becoming soon quite painful. When I first saw him he had but little functional use of the right arm, but almost full use of the right leg. At this time the seizures occurred once daily.

I began the treatment of his case by giving the bromide of potassium (gr. xx. t. d.), and while this had the favorable effect to lessen the frequency and severity of the attacks, it also had the still more unfavorable effect to enfeeble muscular strength on the affected side, causing the foot actually to drag. Having pursued this method of treatment for one month, with the unhappy results before stated, I decided to use the hydrobromic acid. This measure had the immediate effect not only to control effectually the convulsive attacks, but also to allow of a return of the muscular strength to the point at which it was prior to the use of the bromide. While in this state of marked improvement, he contracted a case of diarrhœa, which an over-zealous friend undertook to treat by giving freely of a mixture containing opium. He at once became very drowsy, which state in the course of twelve hours was followed by apoplexy, and this at the end of another week proved fatal. The question here arises, what is the explanation of the

difference between the results from the use of this acid and the bromides?

Squibb has pointed out the fact that bromide of potassium given for a long time weakens the muscular tissue, and sometimes produces other changes through undue alkalinity of the blood and secretions. (*Transactions* N. Y. State Med. Society.)

Since hydrobromic acid, not being associated with an alkaline base, is incapable of producing prostration of muscular strength, and since it has proved its virtues to be in some other respects even superior to the bromides in neurasthenia and post-hemiplegic conditions, the advisability of employing it in exchange for the bromides in these ailments is, to my thinking, free from all doubt. As has been the experience of other observers, so the writer has found this acid to be more highly serviceable than the bromides in gastric irritability.

Concerning the value of this drug as a remedy in the management of epilepsy, the opinions of clinical observers seem to be pretty evenly divided. My own experience tends to corroborate the view that this drug is decidedly less efficacious than the bromide of sodium in this disease. Thus in a marked case of epilepsia mitior which occurred in a female child 14 years old, and having a dolichocephalic head, this acid, in doses of half a drachm four times daily, as the contant result of several trials, greatly increased the number of the attacks. In a case of epilepsia major I prescribed it in drachm doses, given four times daily, with no perceptible influence. In a paper on "The Use of Hydrobromic Acid in Nervous Affections" (*Med. News*, June 20, 1883), Dr. C. L. Dana, after having used it in six cases, concludes that in epilepsy this remedy "cannot be used as a substitute for the bromides, except in the more controllable cases; yet that it undoubtedly has a controlling influence over the disease, and he does not feel certain that if given in equivalently large doses it might not be as efficient as the alkaline salts."

Prof. H. C. Wood (*Med. News*, February 23, 1884,) advocates in vigorous terms the dilute hydrobromic acid, after Wade's formulæ as modified by Fothergill in the treatment of an obstinate cases of epilepsy, though in enormous doses, not less than three ounces per diem, and claims for it better results than from the use of the bromides. In the hands of Allan MacLane Hamilton, ordinary doses of this drug gave negative results in these cases.

A word as to the administration of the drug. The observations by Randolph (MED. AND SURG. REPORTER, vol. l., page 123,) show the best time for administering it to be, after salivary digestion, which is arrested by the acid, is completed, and when free, acid begins to be formed in the stomach—about three-quarters of an hour after meals. I have given it in doses varying from one-half to one drachm at varying intervals. It should, of course, be well diluted, preferably with milk.

CONCLUSIONS.

1. Hydrobromic acid should be employed as an alternate substitute for the bromides in the treatment of diseases in which their effects have been shown to be parallel.

2. It should probably supersede the alkaline bromides in neurasthenia and post-hemiplegic disturbances of a convulsive character; also (as an arterial sedative) in congestions of the pelvic viscera.

3. Except when given in colossal doses—a method not practicable in private practice—it appears to be less efficacious than the bromides of sodium and potassium in epilepsy.

4. Owing to the fact that its action is more evanescent than that of the bromides, it should be administered at intervals of not more than four hours.

1529 *North Eighth Street.*

THE RATIONAL USES OF ALCOHOL IN PULMONARY PHTHISIS.

BY L. HUBER, M. D.,

Of Fort Scott, Kas.

So diverse and often so unphilosophical are the uses of alcohol in wasting diseases of the lungs that an effort to inculcate right ideas relative to this very useful agent becomes highly necessary. There is a gradual enlargement of our knowledge of this agent and its disposition in the economy. There is likewise a corresponding expansion of our views of consumption of the lungs. Certainly, with this unquestionable advance, medical men should display more judgment and care in the employment of this remedy, and should achieve far better results. With a view to formulate a few principles to guide the practitioner this discussion is ventured.

Alcohol when taken into the healthy human system pursues a certain course. Whether we agree that it is a food or not, it is a substance that ranks with hydrocarbons. Being highly diffusible, it soon finds its way through the system. Authorities argue pretty generally that it undergoes combus-

tion in the lungs—that is, up to a certain limitation it is oxidized, and to that extent acts as a food. The average quantity of absolute alcohol that can be thus disposed of by the healthy organism is within two ounces for twenty-four hours. Knowing the percentage of pure alcohol in the different species of drink, one can readily calculate the respective amounts of each to give, to keep within the proper limitation.

Accepting the weight of authority which favors the views expressed above, let us consider the conditions that tend to modify the utilization of alcohol in the human economy. Evidently there must be modifying causes. Observation tells us that certain persons have a greater tolerance for the agent than others. It also shows that climatic conditions also influence the system. Then comes mode of life, disease conditions, habits, and kind of nutriments, etc. Also the purpose aimed at will have something to do with the amount to be prescribed.

The diseases engendered by the abuse of alcoholic stimulants gives us a key to a solution of part of the problem. Some persons have tendency to stomach troubles, to disease of the liver, to abnormal fatty growth in one or another of the organs, or rather a susceptibility to fatty degeneration of certain parts. Inasmuch as the brunt of injury falls upon the stomach, liver, heart, and brain, in even moderate use of alcoholics, it follows that in persons constitutionally weak in these parts a greater hurt will follow than in those constitutionally stronger, or if not a greater, certainly a morbid change will be earlier superinduced. Here then is one condition of tolerance of the agent.

Climatic conditions also favor the amount of alcoholics that the system can consume. In a temperate climate, with a high and dry atmosphere, where the drinking water has no tendency to engorge the liver and render it sluggish, where the atmosphere is rarefied so that the chest must expand to the fullest limitation in order to receive air enough to oxidize the system, where the mode of life is rustic and outdoor largely, alcoholics can be taken far more freely than under opposite circumstances. In certain mountain regions there is an almost absolute tolerance of the agent. Instead of an impression on the nervous system and consequent intoxication, there are improved nutrition and an inexhaustible feeling of comfort and well-being. Consider the country, climate, atmosphere, elevation above the sea, the mode of life incident to the Bible peoples, and it is easily understood how wine, not water, could become the emblem of life. Theorists may dispute the question of fermented and unfermented liquors, but the true solution of the problem is simply that the external surroundings of the race gave it impunity from many of the curses of alcoholic drink.

The kinds of food accessible to a person or habitually used by him will have something to do with the amount of alcohol he can safely consume. This proportion is easily demonstrated. Suppose an individual has healthy digestion ; suppose also that he employs such foods that supply waste and demand in his system. Under ordinary circumstances tissue metamorphosis will proceed normally. Suppose, however, that he is forced upon a fat-producing diet somewhat exclusively, without much or any change in the other circumstances of his life. Evidently the liver will have extra work to perform. It will have its functions taxed perhaps to the fullest extent. Fat deposits will take place. Certain tissues will degenerate. Now the ingestion of a rich hydrocarbon like alcohol will be simply adding further trouble. Under these circumstances the more diffusible, combustible *ingestion* will be worked up, to the neglect of the more bulky. That the functions of the system should be thereby greatly disturbed, is not a matter of wonder.

Having specified the circumstances that modify the utilization or consumption of alcoholics in the economy, let us proceed to the application of the principles we have reached. Recently, the theory of pulmonary phthisis has undergone revolution. Of whatever kind, whether tubercular, pneumonic and non-tubercular, the weight of authority is in favor of the view that there is not only impoverishment of the blood and a lowering of the vital principle, but also a septic condition—a degree of blood-poisoning which leads to certain havoc in the system. The two great indications therefore in the treatment of pulmonary phthisis are increased nutrition and antisepsis. The latter indication is receiving earnest, united study by medical men the world over, and not without promising results. In a patient whose lungs are beset with chronic inflammation, due to a lingering pneumonia, in the majority of cases catarrhal, resulting in points of softening and breaking down (chronic interstitial pneumonia, caseous pneumonia, cheesy softening, of pathologists), antisepsis can fulfill two conditions :

1. It can destroy the infection of the morbid products until these are cast from the system ; and,

2. It can preserve other portions of the

lung tissue from further invasion and by keeping down blood-poisoning lower the grade of waste, if not check the progress of the disease altogether.

If the antiseptic agent combines with itself the properties of a nutrient or food, it therein possesses a two-fold value.

Let us now consider our agent. In the lungs of a healthy person alcohol undergoes oxidation—is, in other words, consumed. The lungs are limited in their power to effect this change. In a diseased condition, before the other organs have materially lost their healthy functions, it must be supposed that about the same amount of alcohol will diffuse through the tissues and find its way to the pulmonary organs. The lungs being partially disabled in their functions, and the process of oxidation hindered to some degree, it evidently follows that a portion of the alcohol will remain unchanged. As unaltered alcohol diffused through the lung tissue, it must evidently have an influence much the same upon the infective, morbid products as it has when used as a preserving fluid in which animal tissue and insects are kept. This is certainly reasonable. Being antiseptic to some extent, being a preservative of animal tissue, it certainly follows that some of its good effects in certain cases are due to this property. Moreover, it is probable that owing to the diffusion of morbid products and the consequent interference with the respiratory function and attending oxidation of the system, the oxidation or consumption of alcohol is greatly increased. The system in want of a necessary supply grasps, as it were, after the subtile agent. The tolerance, so often observed in phthisical subjects, of alcohol, is probably due to this condition. We have an illustration of a similar kind in another agent. When iron is demanded by the system it is often noticed that a far greater quantity is consumed than under less favoring circumstances.

When the process of nutrition is lowered, it follows that an easily convertible food is better worked up than one of bulk and coarseness. In pulmonary phthisis, the fat deposits in the system are first exhausted. Alcohol as a nutrient is a fat-producer. Hence it is that, as a food, in cases to which it is suitable, there is often such a perceptible increase, not only of the bodily forces, but also of the bodily weight.

So far we have not spoken of alcohol as a stimulus pure and simple. The routine practice of the day often puts it forward as this alone. As such an agent it is grossly abused. It is strange how few physicians have well-defined ideas of it even in this application. It is the writer's belief that when pulmonary phthisis proceeds so far that alcohol can serve only as a stimulus, the case is beyond help, and must necessarily proceed to a fatal termination. Besides there may be other much more suitable agents to meet this indication.

From the foregoing discussion it follows that the rational uses of alcohol in pulmonary phthisis must be guided by the following conditions:

1. Begin early in the disease, when the first evidences of consolidation and subsequent softening of the lung tissue can be ascertained.

2. Ascertain the capacity of the system to consume alcohol. This will need close scrutiny into action of the liver and lungs. If there be a degree of tolerance greater than that of health, administer the agent to the extent of it, but do not carry it beyond. If no tolerance exists, and the functions of the system are disturbed by a careful administration of the remedy, examine into the external conditions of the patient—the food to which he has been, and perhaps yet is, habituated; the climate; the likely action of the drinking water on the powers of alimentation and the liver; the atmosphere and altitude. By changing these, which may often be radically done by a removal of the patient to another country, to a mountainous, elevated region, where an out-door life is endurable, this want of tolerance may be overcome. Indeed, it is known that persons have been thus saved from further progressive inroads of the disease. In certain mountain altitudes there is, as already remarked, such a degree of tolerance, that intoxication from alcohol could follow only the grossest abuse of the agent. The writer has the record of several cases removed from the low Atlantic seaboard to the table lands of the Rocky Mountains, in which the capacity to use alcohol as a nutrient increased from less than three ounces of good whisky daily, to the average quantity of twenty-six ounces in the twenty-four hours, accompanied by the most marked improvement of the patients in every respect.

3. When the appetite improves, the digestion is healthy, the cough and expectoration lessen, the frequently attending dyspnœa disappears, and the respiration is slower and deeper, under the use of alcohol, no better agent can be found for that particular case. In alcohol the patient will find a new lease of life, if not salvation from the disease. If, moreover, a cavity has formed in the lung

tissue, and the sputa therefrom lose their fetid character upon the ingestion of alcohol, there is the further evidence that the agent is keeping in check systemic infection, and thus preserving the system from the first rapid inroads of the disease.

With a few facts thus formulated, a physician should surely manage his cases of pulmonary phthisis far more satisfactorily than by pursuing the usual rountine method. Besides, it will be a serious matter with him to use indiscriminately this useful agent. There are some serious considerations to be recalled. It is not a trifling matter to insist upon the use of an enslaving agent like alcohol. The course must be justified by well-defined aims. How often under the indiscriminate use of the agent has a life of drunkenness been engrafted! This has never followed, the writer will venture to say, the scientific therapeutic administration of alcohol. The late Dr. Flint asserts that it is extremely rare for a taste of alcohol to be engrafted when its use is properly defined, and his experience has been extensive.

Thoroughly convinced by observation of the soundness of these views, the writer will submit them to the reading public for timely consideration.

MEDICO-LEGAL NOTES.

BY HENRY A. RILEY, ESQ.,
Of New York.

CURIOUS GRAVE ROBBERY CASE.

A curious grave robbery case has just been decided by the New York Supreme Court, General Term, at Syracuse. Some little time since Gen. William Irvine, an ex-Congressman and a prominent person in Central New York, died, leaving a large estate. Directly after his death, a Mrs. Fitzgerald stated that Gen. Irvine was indebted to her in a large sum for services rendered as a nurse during several years prior to his death, and that she had loaned him $2,400 on the day he died. She further stated that unless her demands were met she would make a public scandal. Nothing seems to have been done at the time to appease her, and about a year after Gen. Irvine's death, Mrs. Fitzgerald instituted an inquiry into the cause of his death, alleging poison administered by his wife or daughter. Dr. Edmund A. Reilly, a coroner of Chemung county, had the grave opened in the night time and the body taken to the receiving vault, where an examination was made. The coffin was also searched, and its lining was cut open in an effort to find a will which it was supposed to contain. The body, the physicians say, showed that one autopsy had already been made upon it. The coroner removed some of the viscera and carried them away with him. The body was then replaced in the coffin and returned to the grave. When these occurrences became known, Mrs. Fitzgerald was indicted for the desecration. It was shown on trial that the parts removed contained no poison, and the defendant was unable to show any valid reason for disinterring the body, and she was convicted and sentenced to two years imprisonment in the Monroe County penitentiary. An appeal was taken from the sentence, but Mrs. Fitzgerald was unable to secure bail, and accordingly had to go to jail. The sentence has about half expired, when the decision of the Appellate Court is announced, to the effect that the conviction was proper and legal.

HUMAN BONE.

The *Microscope*, in its latest issue, has a brief article upon the question, "Can human bone be told from other bone by aid of the microscope?" and says that a general negative must be given. The writer declares, however, that if two specimens are shown, and one is known to be from man and one from another animal, the microscope will show to which one each specimen belongs.

HEALTH COMMISSIONER FOR NEW YORK.

The Health Officers of New York city are in danger of being abolished, if the bills now introduced in the Legisture receive the attention they are expected to get. It is proposed to close out the present Board and appoint a single Health Commissioner, who shall serve for six years and receive a salary of $8,000. He is to have a Deputy at a salary of $5,000. The office of Attorney for the Board is abolished, and the Corporation Counsel is directed to assign one of his deputies to the new Commissioner. Corporation Counsel Lacomte has expressed himself in opposition to the bill, and says that the duties of the position can not be properly performed by any attaché of his office, unless an appropriation is made for the purpose.

One of the most important subjects of health legislation is child labor, and the safeguards which should be thrown by statute around the employment of minors. This matter was fully discussed in the annual report of the Bureau of Labor Statistics of Connecticut by Prof. Arthur T. Hadley, the very competent head of the Bureau. Prof. Hadley states that there is a law in Connecticut forbidding the employment of children

under thirteen years of age. This law was framed in the interest of the working classes, and yet it is very strenuously resisted by them. The operatives, it was thought, were desirous of keeping their children out of the mills, yet they are the very ones to insist on their working. The secret of this is the need of the money which the children earn. As the report says, the opposition comes from those "to whom the twenty-five cents a day that a child can earn by working in the mills is a present consideration that will outweigh anything else; who will not merely connive at evasions of the law, but make every effort to obstruct its enforcement."

An instance is given of a twelve-year-old boy who was actually supporting a family on wages of five dollars a week. When the law came into force he was driven out of the factory by the State inspectors. Prof. Hadley says that the "general object to be obtained is so good that we must be prepared to enforce the law, even though it may create great hardship in individual cases." The law Prof. Hadley thinks can be enforced, and even a fourteen-year rule, but a higher rate it would probably be impossible to enforce.

OLEOMARGARINE.

The recent decision by the Pennsylvania Supreme Court that the law prohibiting the manufacture of oleomargarine is consitutional is in direct contrast to the decision by the New York Court of Appeals, but it will be very effective if public sentiment sustains it, as seems to be the case. In New York, notwithstanding the adverse decision of the courts, the law still requires oleomargarine to be branded, and the sale is very much diminished.

In New Jersey the law requires the dealer to inform the consumer that he is buying counterfeit butter, and as few persons buy the substitute intentionally, a vigorous enforcement of the law has made the sales much less. The federal law passed at the last session of Congress is helping very much in the general disaster attending the trade in oleomargarine.

"APPLICATION OF THE ANTISEPTIC PRINCIPLE IN PRIVATE PRACTICE."

BY GEO. H. KIRWAN, M. D.,

Of Wilkesbarre, Pa.

To those who are unbelievers as to suppuration being a form of bacterial fermentation which never takes place except by the growth and development of micro-organisms, what here follows will be of little interest.

The busy every-day practitioner cannot devote the time (even if he possess the necessary knowledge and skill) to deep microscopical investigations, micrococcal cultures, etc., pursued by the pathologist and microscopical student, investigations which must convince him, beyond all question, of the bacterial origin of all suppurative troubles, and by the contact and development of these organisms prevent the primary union of wounds.

To my mind there is nothing clearer than that (aside from the microscope, which gives ocular demonstrative proof of the bacterial origin of these troubles) simply drawing our conclusions from the results of their treatment by germicide solutions and dressings, the germ origin of suppurative troubles is demonstrated to be correct.

Let the medical man who doubts that a case of puerperal septicæmia could have resulted from the contact of his surgically unclean hand with the genital tract during parturition, take the precaution in the treatment of subsequent cases to render and keep his hands and instruments *surgically* clean, and observe the absence of such complications in the labors thus treated; or recognizing (as many fail to) that he may have caused the trouble by carrying germs to the seat of the disease, let him use (without any constitutional treatment whatever, if he will,) simple but thorough irrigation of the uterus and whole genital tract with a germicide solution, and observe the temperature drop at once to normal, and all serious symptoms subside, and his skepticism will vanish with the trouble he thus relieves.

Or, again: let him perform or witness almost any surgical operation, *e. g.*, a Teale amputation of the leg under proper antiseptic precautions and dressings, and see the primary dressing left undisturbed for two or three weeks, and then being removed, complete primary union without the formation of one drop of pus having taken place, and contrast this with results of former methods of wound treatment, and draw his own conclusions.

It is fast becoming a settled conviction in the more advanced minds in the profession, that the practitioner who to-day has septicæmia follow his wound treatment, or puerperal fever his accouchements, and resulting fatally, should be held criminally responsible for these preventable consequences.

Amongst the physicians with whom I have talked on the subject who have not adopted

the antiseptic treatment, the reason almost invariably given is, "It's well enough for hospital treatment; if there is anything in it they get the benefit of it; but for or during private practice it is too expensive, and could not be carried out." Where the object is the saving of life or limb, nothing should be too onerous or expensive to the conscientious physician. But aside from this, the object of this paper is to prove this idea fallacious, viz., that antisepsis in private practice is both inexpensive and practicable,

With reference to the cost of dressings, antiseptic dressings are in reality cheaper than ordinary wound dressings, when we remember that one of the former properly applied answers frequently in lieu of twenty of the latter, and many physicians not heretofore practicaily familiar with the dressings will be surprised that the list here given contains all articles necessary for carrying out the principle and obtaining the extraordinary results claimed for antisepsis in wound treatment, and can be obtained at a cost of about five dollars.

1. Bottle compressed tablets bichloride mercury each containing 7.3 grains, so that one dissolved in pint of water will make the standard one to one-thousandth solution. These tablets are readily soluble, and are much more reliable and convenient than carrying a solution. I have always used those made by Jno. Wyeth & Bro., of Philadelphia. I do not know of any other manufacturers of them. They were first suggested by Dr. Chas. Meigs Wilson, of Philadelphia.

A soft rubber bag fountain syringe, capacity one gallon, with six or eight feet of hose attached with adjustable tubes. The one I use is made by Whitall, Tatum & Co., of Philadelphia, and has infant's, rectal, vaginal (large and small), urethral, and small irrigating tubes for attachment, to which I have added a stomach-tube attachment and a long flexible uterine tube, so that with this I have by gravity washed out the uterus, vagina, rectum, bladder, urethra, and stomach, besides using it for constant irrigation with the bichloride solution in the cleansing antiseptically of all wounds before dressing.

3. Violin strings; to be obtained from any musical dealer — four different sizes being all that is needed. They are prepared by saturating in oil juniper for twenty-four hours, which removes the animal oil; kept in a bottle of stronger alcohol, and saturated in the standard solution when required for use, and used for ligatures, sutures, and capillary drainage. When needed for the ligature of large vessels, they are made stronger and less readily absorbed by treatment with chromic acid.

4. Cheese-cloth, sold cheaply by all dry goods dealers, saturated in the standard solution, and used for compresses and bandages.

5. Absorbent cotton, saturated in the standard solution and dried. There are many good makes. I use and prefer Jno. Wyeth & Bros. A prepared wool, known as the Globe antiseptic wool, made by Henry Thayer & Co., Cambridgeport, Mass., though possibly less absorbent, never becomes lumpy, is more elastic, and perhaps is preferable to cotton for dressing large wounds.

6. An ounce or more of iodoform in an ordinary pepper box for dusting, or as I use and prefer, one of the cheap insect-powder guns sold in all drug stores.

Armed with the six articles I have just named, and which can all be carried in small compass in the ordinary bag, I am prepared to state from experience that for all ordinary uses in private practice the antiseptic principle can be successfully carried out, the entire practice after all only being surgical cleanliness. Carbolic acid solutions are never absolutely required. Cutting instruments cannot, it is true, be immersed in the bichloride solution, but they can be effectually sterilized by immersion in boiling water; the same is true of the needles used. I have omitted mention of the "protective" used by many, fearing irritation from the direct contact of the dressings, because I have never observed this, and do not use it, but it can be secured for a trifle if preferred. Capillary drainage is sufficient for nearly all wounds dressed antiseptically, and where tube drainage is desirable, the tubes are easily sterilized.

It is perhaps unnecessary to state that the hands must be thoroughly sterilized, and the hair removed from the field of operation, nothing on the surface being more tenacious of dirt, which always means micro-organisms. It will be found, too, that it is attention to what may appear trivial details that will make this treatment successful. Where I have failed with this treatment to prevent suppuration after operation, I have always been able to look back over the case and recall some apparently trivial neglect that defeat the object in view.

—At a recent meeting of the Académie de Médecine, M. Sagneau, the well-known statistician, stated that among the educated classes one-fourth more are unfit for military service than among the masses. In Prussia, the proportion is much greater.

Medical Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated meeting, February 9, 1887. The President, J. Solis-Cohen, M. D., in the chair.

Dr. H. A. Kelly presented the

Results of Some General Work in Abdominal Surgery, with Cases and Specimens.

The notes of cases here offered for your consideration were collated at very short notice to fill a vacancy in the evening's programme. This explanation, however, I do not intend as an apology, for the subject is one of extreme importance, in which, as a specialist, all my own interest is concentrated; and I believe that I shall be able, in a few minutes this evening, to draw your attention to a list of cases remarkable for its variety, including one or two topics quite new.

Many here to-night remember the time when the large cystic ovarian tumor was considered the only indication for abdominal section, and, if other conditions were accidentally discovered, the incision was simply quietly closed. The dangers of the operation itself were so great that surgeons were loth to interfere until the patient's wretched condition seemed to warrant the risk.

As, however, our race cultivated a familiarity with the peritoneal sac, and learned its limits of toleration and intolerance, a bolder and more successful work was entered upon. With dropped pedicles, innumerable ligatures for hemorrhage, peritoneal toilet, drainage-tube, and, above all, an unremitting care to secure *microscopic* cleanliness throughout, we have become masters of the situation, and our failures, when they occur, are no longer *mysteries*. And with these improvements has come a recognition of a greater variety of indications for abdominal section, until, as to-night, I am able to present, out of twenty-eight successive cases, at least nineteen separate morbid conditions. Before calling your attention to the list of my cases (which shall be only cited briefly by name), I would ask you to consider with me a few important points bearing directly upon the work.

In the first place, as to *percentages*. While I have a personal pride in my work which induces me to say that it will bear the strictest criticism, yet I cannot but deprecate the bitter spirit which animates so much of the percentage discussion. The time *was* when, by this means alone, by means of the striking differences which existed, we were enabled to determine, in the absence of personal experience, the relative value of *methods;* but that time has *passed*, and with the closure of the chapter on ovariotomy, this spirit of emulation survives no longer in the interest of *science*, but is *personal* and unworthy of our cause. Further, it is manifestly absurd to compile statistics from a class of heterogeneous cases.

In the removal of small tumors in the pelvis, in the removal of ovaries and tubes not to the naked eye diseased, we are most often compelled to operate for *pain*. The patients themselves, *seeing* nothing amiss, are very loth to submit to "being opened" until their misery makes life a burden—at least this has been my own experience with women, to whom I always explain, in the fullest possible manner, the exact nature of what I propose to do, and its consequences. It is gratifying to the operator, who has finally been driven to this expedient, to find gross lesions suitable for class demonstration, but the most typical relief often comes where the disease cannot be so easily demonstrated; and in cases where there are palpable tumors, the surrounding infiltration and cellulitic inflammation are often serious enough to delay convalescence, for a long time defeating the operator.

Thus, if I were asked, in my own work, which of my cases had given the most gratification—that is, where had the relief been most typical and striking from a condition of suffering—I would point out a patient who was for more than two years unable to take a step on account of the great pain in the right ovarian region; in addition, she was a most wretched sufferer throughout the whole time. There were no gross lesions in the ovaries, and it was long a question with me whether she had not some other serious organic disease, which question I debated under the most varied and patient efforts at general and local treatment, until, with the removal of ovaries here shown, she rose up as if a great weight had been lifted off her, and went home to Barnesville to her parents and friends, a walking miracle.

Another case, well illustrating this point, is that of Mrs. W., here shown. She suffered, as she only can describe to you, ever since her first menstruation, from pains which left her a most degraded picture of misery when she came to my office. I found the remains of chronic ovaritis and the wiry tubes of a chronic salpingitis and perisalpingitis, which had contracted down so tight

and adhered to so many surrounding structures that they were exposed and removed with the utmost difficulty. This patient has gained eighty pounds since the operation.

These results, and some others I might detail had I time, are undeniably brilliant; but cures are not always so typical, and I am still often satisfied in this, my work, if I can remove but one element (perhaps the most distressing) of my patient's sufferings. If my patient can only come back to me and say, "You have taken away that dreadful pain in my back and stomach; life is now bearable, before it was unbearable," I am well content.

Mrs. B. (here shown) exhibits this well. She had a rapidly growing tumor in the right ovarian region, which seemed, in a most unaccountable manner, to prostrate her general health. I decided this to be a case of extra-uterine pregnancy, and I believe my section proved it. She is now like another woman, though still under treatment for an induration of the left apex, undiscoverable before operation.

I do not, Mr. President, therefore, claim wonders for this field of work. I claim for it what is asked for other fields of our art—that the *results* justify the means. It is of *results* I wish now to speak, with a brief preliminary as to *difficulties*.

The difficulties encountered in handling small pelvic tumors are often very great, far exceeding that of removing an ordinary cystoma.

First, the abdominal walls, which have never been distended, press tightly down upon the contents, and the recti pinch the fingers like a vise, utterly defeating any effort to catch or raise pelvic viscera, and this in spite of ether and chloroform. I have been obliged twice to overstretch the recti before I could proceed.

Secondly, in case of chronic peritoneal inflammation, the bleeding from the more superficial vessels of the abdominal wall may be extreme.

Thirdly, the intestines, in this close sac, often cling to the fingers until they feel, as if they were clothed with several pairs of gloves, and just as useless.

Fourthly, when the patient is very obese, the embarrassment of the operator is greatly increased, requiring a much larger incision, prolonged manipulation, with difficulties of closure and subsequent dangers.

Fifthly. Cellulitis, so common a concomitant, so draws down and anchors everything in the pelvis that the structures are elevated with extreme difficulty, and only a pedicle, in the *technical* sense, can be secured. The danger of secondary hemorrhage from this kind of a tie is, I know, very vividly before the minds of all operators of experience. It is, at times, about like tying the apex of a broad-based pyramid. I tied off some broad ligament structures on a fibro-cystic tumor the other day which impressed me for all the world like putting a ligature on a paper wall.

Lastly. These smaller diseased structures often become parasitic on neighboring tissues and organs for their blood-supply, and when they are torn loose, the bleeding is alarming; and it may be deep down in the pelvis, possibly requiring an enlargement of the original incision, and then only seen with the utmost difficulty of exposure and illumination.

With this introductory, I will read a table of cases operated upon by me in 1886. All the operations were performed within the seven months and a half during which I was at home, and almost all in my private hospital in Kensington. The condition of the patients is either settled or weekly improving, so that I feel at liberty to speak of *results*.

In but two cases of the above list will I dwell any more in detail.

In one, James Dougherty, I did what has, I believe, never been done before: opened the abdomen upon a diagnosis of hypertrophic cirrhosis of the liver, with the intention of puncturing—hepato-phlebotomy.

The patient, about forty years of age, had a very large ascites, which had been treated for some weeks, but never tapped; and with full confidence in the safety of a simple incision, I make a free opening, large enough to admit two fingers, just below the umbilicus, thoroughly emptied the peritoneal cavity of two bucketfuls of fluid, and on reaching the liver found the organ contracted and hobnailed; I consequently closed the incision, which healed perfectly. The fluid reaccumulated very slowly until the man died, some weeks after, in the natural course of the disease. My friends, Dr. R. P. Harris, and Drs. Freeman and Bradford, residents of the Episcopal Hospital, were present. I had long intended to use this direct method of abstracting blood from the liver, in view of my experiences in hospital and private practice since, before Dr. George Harley recommended plunging a trocar into the liver through skin, subcutaneous tissues, and two coats of peritoneum, in the right hypochondrium, with the same end in view—hepato-phlebotomy. If, however, I am go-

No.	Name.	Diagnosis.	Operation.	Date.	Result.	Remarks.
1	Mrs. B.	Cystic papilloma of broad ligament.	Incomplete removal.	Jan. 2, 1886.	Died.	Private hospital. Death in six days of peritonitis.
2	Mrs. D.	Menorrhagia.	Both ovaries and tubes removed.	Jan. 31, 1886.	Recovered	Private hospital. Worn to a skeleton by hemorrhages which had lasted for years. two weeks at every menstrual period. Perityphlitis after operation; now in blooming health. Cured.
3	Mrs. C.	Ovarian tumor.	Removal.	Jan. 14, 1886.	Recovered.	Private hospital. Operation by Dr. C. B. Nancrede assisted by me. Fecal fistule six months. Recovered.
4	Mrs. H.	Cystic ovary.	Removal.	Jan. 23, 1886.	Recovered.	Private hospital. Ovary large and full of extensive hemorrhages. Cured.
5	Mrs. W.	Hæmatosalpinx.	Removal.	Feb. 17, 1886.	Died.	Private hospital. Peritonitis.
6	Mrs. B.	Hydrosalpinx.	Removal.	Feb. 24, 1886.	Recovered.	Private hospital. Tubes large as sausages Cured.
7	Miss S.	Menstrual epilepsy.	Removal of tubes and ovaries.	Feb. 24, 1886.	Recovered.	Private hospital. Remarkably improved after a temporary relapse. Condition yet doubtful.
8	Mrs. P.	Abscess of right ovary.	Removal by enucleation.	Mar. 27, 1886.	Died.	Private hospital. Found, post-mortem, large pus sac in pelvis.
9	Mrs. B.	Three months tubal pregnancy.	Removal.	Mar. 20, 1886.	Recovered.	Private hospital. Pregnant. Later delivered of a large female child.
10	Mrs. U.	Cellulitic adhesions of ovaries.	Adhesions freed.	Mar. 13, 1886.	Recovered.	Private hospital. Now well.
11	Mrs. W.	Ovaritis, salpingitis, and peri-salpingitis.	Removal tubes and ovaries.	Mar. 17, 1886.	Recovered.	Private hospital. Well; has gained eighty pounds.
12	Miss W.	Hydrosalpinx and stump of ovary.	Removal.	Apr. 20, 1886.	Recovered.	Private hospital. No pelvic pains whatever, but frequent headache. Improved.
13	Mrs. W.	Dermoid cyst.	Removal.	Apr. 25, 1886.	Recovered.	Private hospital. Patient operated on by Dr. T. R. Neilson, assisted by me.
14	Mrs. G.	Ovaritis chronica.	Removal tubes and ovaries.	Apr. 17, 1886.	Recovered.	Private hospital. Vastly improved.
15	Mrs. T.	Chronic cellulitis.	No attempt at removal.	Apr. —, 1886.	Recovered.	Private hospital. Improved.
16	Miss S.	Pelvic abscess.	Stitched to abdominal wall.	Mar. 21, 1886.	Recovered.	My home. Died in Pennsylvania Hospital in summer.
17	Mrs. W.	Pelvic cellulitic adhesions.	Separated; no removal.	Apr. 21, 188 .	Recovered.	Private hospital. Since bore child, and feels well.
18	Mrs. H.	Pyosalpinx and abscess of ovary.	Enucleation of large fetid abscess.	May 5, 1886.	Recovered.	Her own home. Cured.
19	Jas. D.	Cirrhotic liver.	Exploratory incision.	Oct. 29. 1886.	Recovered.	His home. Improved from free tap. Died natural course of disease.
20	Mrs. G.	Pelvic abscess.	Abscesses opened into rectum.	Oct. 4, 1886.	Recovered.	Private hospital. Improved.
21	Mrs. M.	Tubercular peritonitis.	Opened; cleansed.	May 12. 1886.	Recovered.	Private hospital. Recovery apparently perfect, with relapse in eight months and again recovery.
22	Mrs. B.	Ovarian pregnancy.	Removal.	Nov. 4, 1886.	Recovered.	Private hospital. Cured.
23	Mrs. B.	Hydrosalpinx; metrorrhagia.	Removal.	Dec. 17, 1886.	Recovered.	Private hospital. Cured.
24	Mrs. B.	Racemose ovarian cyst.	Removal.	Nov. 13, 1886.	Recovered.	Private hospital. Cured.
25	Mrs. T.	Chronic metritis and endometritis.	Removal of appendages.	Nov. 18, 1886.	Recovered.	Private hospital. Cured.
26	Mrs. P.	Papillomatous monocyst of ovary.	Removal.	Nov. 18, 1886.	Recovered.	Private hospital. Cured.
27	Mrs. J.	Retro-peritoneal sarcoma.	Exploratory.	Oct. 4, 1886.	Recovered.	Her home. Now being tapped.
28	Mrs. S.	Papilloma of peritoneum.	Exploratory.	Dec. 24, 1887.	Recovered.	Private hospital. Temporary improvement.

ing to draw blood from this organ in a state of inflammation, I prefer an incision free enough to allow me to handle the organ, and, under full control of the eye and touch, to direct the trocar to the proper place, free from the danger of wounding other structures or large vessels. The incision should be made just above the umbilicus.

Regarding the last case, that of my office nurse here, number twenty-one in the table, I will content myself by briefly remarking that she suffered constantly for four years with a dragging pain in the left side, and two years ago last December she was tapped for what was believe to be a large ovarian tumor. The fluid was straw-colored and coagulated spontaneously in the bucket. She came to me from Ogdensburg, N. Y., twenty months ago. There had been no reaccumulation of the fluid, but she suffered constantly with dragging pains in the left side. I found here masses attached to the left cornu uteri, which I mapped out in my book; but, to my astonishment, I found, in the course of a few weeks, while under treatment, that the tumor diminished and seemed to have shifted its site. Bimanual examination, while still revealing well-defined masses in the neighborhood of the uterus, yet yielded such a different find that I was disposed to distrust my records. As her suffering increased, I made an incision last spring, and found the intestines universally adherent, like one great sac, but free from the abdominal wall; the pelvic structures were so bound up that I could define nothing. Some serous

fluid oozed up into the incision and coagulated *in situ*. This was carefully cleaned out of the whole peritoneum, a piece of membrane, containing isolated tubercular granulations, snipped off for microscopic examination, and the incision closed. She apparently made a perfect recovery, and returned to New York, doing a great deal of hard work all summer (had not been so well for twelve years). She returned to me upon my return from Europe, and, until seven weeks ago, remained in perfect health. The old pain then began to distress her again, and with it was a continuous elevation of temperature. After waiting until it was impossible for her to drag herself around any more, I again made an abdominal section, by a smaller incision to the right of the old incision, for the purpose of cleaning out the cavity and dusting well with iodoform. She insisted upon preparing everything for the operation herself, and lay down upon the table and submitted to the section *without* a general *anæsthetic*. I made multiple hypodermatic injections of a few drops of a four per cent. solution of cocaine in the line of the incision. The pain of the incision was but slight. It increased with the introduction of two fingers within the peritoneum, but was easily bearable. In fact, once she warned Dr. R. P. Harris, who was present, not to make her laugh. The only severe pain felt was in handling the matted structures in the left side of the pelvis. Sixty-two grains of pure powdered iodoform were sprinkled over the peritoneal surfaces, the incision closed and the patient put to bed without the slightest shock or discomfort. She insisted on unbuttoning the jackets worn by the operator and assistant, and was as comfortable from that moment until she rose on the sixth day, to take a drive on the seventh day, as if there had been no operation. All trace of the induration has disappeared, and she has since felt perfectly well, although the ultimate result remains very doubtful.

Eleven of the cases referred to in the above table were exhibited to the Society, and showed the scars of their incisions.

DISCUSSION.

Dr. Addinell Hewson said: "I wish to express my opinion in reference to certain points in connection with the paper read. The speaker stated that he has resorted to the operation for the relief of pain in cases where the diagnosis was not definite and the existence of a tumor not positively made out. In an experience with over three hundred cases, I have not seen one in which relief of pain was not directly afforded by the application of clay.

"In reference to the stretching of the cicatrix, it has been my lot to see a good many cases of hernia following laparotomy. In one three or four large herniæ protruded. In this case I resorted to the use of a fifty per cent. solution of silicate of soda applied on strips of gauze, such as the late Dr. Paul Beck Goddard used in his collodion dressings."

Dr. J. M. Baldy said: "I would first refer to the case in which the uterine appendages were removed for metritis. This is a new indication for the operation, and it seems to me that it would be a unique case in which such a procedure would be justifiable. There are many men of large experience who have not seen an uterus which they were unable to reduce to a normal size without recourse to surgical procedure. In regard to cystomata, it is important that as soon as they are diagnosed they should be removed. It has been claimed that rupture of the cyst is followed in a shorter or longer time by malignant disease not only of the appendages and peritoneum, but also of other organs. It is important in pyosalpinx that the appendages be removed on both sides.

"I have seen a good many cases of pyosalpinx operated upon, and in some cases where the disease was unilateral the unaffected tube has been left. In a recent case operated on by Dr. J. Price this was done, and two months later the second tube became involved; on opening the abdomen, it was found impossible to remove it on account of the adhesions present.

"As a rule we should be aware of removing appendages in which, on examination, we can discover no disease. There are cases, however, which will tempt most of us to operate. Dr. Kelly's case of simple chronic salpingitis, in which he had such happy results, is a case in point. A case operated on by myself was just such a one, and terminated just as happily."

Dr. J. Price said: "In Dr. Kelly's cases it is as yet too early to speak positively with reference to hernia, but his incisions have been short. In the December number of the *Lancet*, Mr. Tait gives a review of this whole subject and of hæmatocele. I wish to argue against the removal of the appendages for defective involution. We have many other methods of treatment which will surely accomplish the same result without resorting to such bold measures. I consider this an unjustifiable procedure.

"At present, the surgeon simply presents numbers and percentages of recoveries as representing the exact measure of his skill in operating and care in the after-treatment. Too great importance has been given to bare statistics. The conditions inherent in the patient which determine the result beyond the control of the surgeon are barely considered, nor faults of omission or commission on his part. Perfect evacuation of pus, the utmost cleanliness, and perfect drainage—I mean a high degree of surgical cleanliness.

"The growing tendency to hold the surgeon strictly responsible for every unfavorable result has stimulated abdominal operators to great care and the most careful study of every detail. Hence the methods of abdominal surgery have become well-nigh perfect."

Dr. Kelly said: "I have had no practical experience in the treatment advocated by Dr. Hewson; if it can be shown to be practicable in such cases as I have detailed this evening, I will try it. My efforts, however, have been directed toward the establishment of a cure, and not palliation. With reference to the case of enlarged painful uterus, with endometritis, of which Dr. Price has spoken, I desire most emphatically to make the following statement, and at once prevent any further misconception upon so serious a subject.

"I hesitated in reporting this case lest I should be misunderstood. I do not wish to recommend a sectional operation for subinvolution or metritis in general. I am weekly treating many such cases without any idea of operative interference. In this particular instance the patient had not only been long under treatment in one of our first hospitals, but I had faithfully tried every means at my disposal for two years—counter-irritation, douches, packing, large wedge-shaped excision of the cervical lips, and an Emmet operation on the perineum, hoping by this support, free depletion, and rest in bed to secure a permanent advantage. She was only slightly benefited, remaining a miserable sufferer until I operated, removing tubes and ovaries. The uterus decreased *at once* in size, and is now three inches, with a small hard cervix, and reclines in the sacrum rocking-chair fashion. She has no local tenderness whatever. I attained here a perfect result, which I was unable to reach in any other way, and under similar circumstances I should repeat the procedure. If permanent, this will be one of the most gratifying of my cures."

THE CLINICAL SOCIETY OF MARYLAND.

Stated meeting, January 7, 1887.

The President, Randolph Winslow, M. D., in the chair.

Dr. Robert W. Johnson presented notes on three very interesting surgical cases.

Case 1. Excision of Hip-joint (Patient).

The first case which I have the pleasure of presenting to the Society is that of a boy on whom I did the operation of excision of the hip-joint in July last.

Early in that month, Dr. Platt, leaving town, turned him over to me, with the following history: W. M., 5 years of age, the oldest of three children, the others suffering with scrofulous glands, was first taken sick when 17 months old, when he began to limp, had the starting pains at night incident to hip disease, and was treated at that time for rheumatism, and after the proper diagnosis was made later was confined to his bed two years, and extension applied. The case progressed favorably under the treatment until, as is so often the fact in this class of life, improvement engendered carelessness, and the child was allowed by parents to lapse into his former condition.

When first seen by me his body was emaciated, temperature elevated, some hectic was present, the hip and pelvis on left side raised. Sinuses were discharging from the anterior and posterior aspect of thigh, but there was no marked pain except on pressure. A probe introduced in the direction of the joint disclosed unmistakably the presence of dead bone, a flake of which had been previously exfoliated. The boy was sent to the Church Home, and two weeks after admission, during which time he had the full benefit of comfortable surroundings and got acclimated to his new friends and improved diet (no small item in the treatment of children, for nothing is more depressing than homesickness in the repair of children's diseases)—after, as I say, he was satisfied, with theable assistance of Drs. Garvin, Moale, Lockwood, Gorter, Shippen, and Moseley, I, under ether administered satisfactorily by Dr. Murdock's inhaler, cut down on the joint on the left side by the semilunar incision above the great trochanter. I found it impossible to follow Sayre's advice, dangerous in the probable tubercular origin of most coxalgia in children, of detaching a periosteal cup, but was compelled after turning out the head of the bone to saw it off by a chain-saw immediately above the lesser trochanter. I found the acetabulum devoid

of necrosis, though containing granulation tissue, as I was led to suspect when I had introduced my finger through the first incision of the capsule into the joint, and felt the worm-eaten remains of the head and neck. To prevent the accident of closing the acetabulum by the juxtaposition of the cut surface of the femur and the acetabulum, another piece of bone was removed, making the stump transverse and not oblique. The wound was thoroughly washed out with bichloride solution, dusted with iodoform, a drainage-tube through the thigh introduced and closed with adhesion strips, the limb being extended and between sand-bags.

The boy stood the operation quite well, and did not suffer greatly from shock. The next day the splint, as you see it, was applied, and the wound washed out daily with bichloride. The wound, except where the tube came out, united *per primam*, and nothing happened to mar success until a month later, when the youngster, anxious to hurry recovery, pulled the drainage-tube out. I then took off the splint lest the continual confinement should tell on his strength, and turned him loose on crutches, in order that he might retain as much movement as possible in the joint.

He has been improving in health since, has gotten fatter, sleeps well, suffers no pain, and, except the sinuses, is in excellent health. Whether they depend on tuberculous trouble in the bone or not, I cannot say. I have not found any bacilli in the discharge, though I have not inoculated a guinea-pig with any. He wears a high shoe on his well side to give the other the benefit of its own weight in extension, and has more movement than I expected.

I do not propose to operate further at present, as any excision below the lesser trochanter renders the limb so useless that amputation is almost preferable.

He must fight it out on the line of cod-liver oil and iodide of iron at present; and if he improves in the future as he has in the past, I think we shall score a victory.

By the kindness of Dr. Chambers, I can show you a specimen of bone on which a similar operation had been done. Those who wish to weigh the value of this operation by the statistical method will find useful papers by Yale and Van Arsdale in a recent number of the *Annals of Surgery*. It is not my object to go into the pros and cons of the operation to-night, but simply to show you a result, by no means a perfect success, but one on the whole I condsider as justifying the excision, in that the boy has now no pain, greater mobility, increased chance of recovery, and smaller sources for infection, with more likelihood of overcoming his present enemy than if left to the impossible exfoliation of the bone, the attempt at which, in the opinion of those who first saw him with me, was fast hurrying him to an early grave.

DISCUSSION.

Dr. John Chambers thought it would be of interest to show, in connection with Dr. Johnson's case, a portion of the femur from a colored boy. Some time since this case was reported to the Society, and the excised portion of the bone then shown. There was such an amount of suppuration following upon the operation that the boy's vital powers were at last exhausted. Autopsy revealed amyloid degeneration of the liver, kidneys and spleen, and acute miliary tuberculosis in the lungs. At the time of operation the case gave rather an unfavorable outlook.

The second case, reported by Dr. Chambers at that time, is of the same nature; but the patient is doing well, and is in apparently excellent health.

It is the opinion of Dr. Chambers that in these cases the prognosis is more favorable when the disease is confined to the femur, than when it has progressed to the acetabulum. He thinks death resulted in first case from a remnant of tubercular material left in the bone.

Dr. Randolph Winslow said that Schmidt has pointed out that where the disease has invaded the acetabulum, abscess formation can often be felt through the rectum.

Dr. Robert W. Johnson then read

Case 2. Resection of the Gut.

Mr. C., 59 years old, has had a reducible hernia for fourteen months, wore no truss, but on Tuesday, after jumping, was unable to restore it to his abdomen, his physician failed also, and after waiting until Friday night, consulted Dr. Miltenberger, who kindly suggested calling me in. I saw the case Saturday morning, and found the patient showing the influence of opium he had taken, vomiting yellow offensive fecal matter, limbs drawn up, belly tympanitic, pulse and respiration rapid, a cold sweat on forehead—in fact collapsed. Seeking the cause of the trouble, I found a potato-like tumor, irregular and somewhat nodular, over which a dusky lurid skin was tensely stretched, with its long axis transverse to the body, and lying over Poupart's ligament on the right side. The tumor was tender to the touch, and tympanitic, and the diagnosis admitted of no doubt, a strangulated indirect

hernia lying in the inguinal canal, and not so far down as the external ring, which could be felt free by invaginating the scrotum.

Having shaved and washed with all antiseptic precaution but the spray, using the bichlor. hyd. solution, with the assistance of Drs. Gavin and Claudè Van Bibber, I cut down on the axis of tumor, using a grooved director after penetrating the skin. No vessels of any moment spouted, and soon the sac, looking like a ripe purple plum, dark effusion, and in some places ashy, showed itself in the wound. Carefully separating adhesions, I nicked the internal ring without effect at reduction. The only place left for constriction was the neck of the sac; when on opening the sac it was found, as well as gut and omentum, both sphacelated, and from cribriform puncta in the intestines the slightest pressure forced out liquid fæces. There were no adhesions in the sac, and but little fluid. The only thing to do was to exsect as much of the gut as looked unable to be replaced. Healthy gut at either end of the gangrenous portion was stitched to the side of the wound and to each other, the mesentery intervening was ligated, and all the necrosed tissue excised. A gush of fecal matter showed the improbability of a twist high up. The omentum and sac after ligation with catgut were removed. The stump dusted with iodoform after washing and iodoform gauze dressing applied over drainage-tube, all covered in by a spica, finished the operation.

Hot bottles, injection of brandy, and digitalis did not rally him and he died in a few hours, never recovering from the shock of his lesion.

To show how desperate I considered the case when I first saw it, I stated the facts and the probabilities, and only operated at their solicitation. The priest administered extreme unction before I began, and I operated more to let the family console themselves that all had been done than from any hope I entertained of success.

I believe in operating in strangulated hernia as I would in tracheotomy, for sometimes it resurrects.

I did not attempt a reunion of gut, as I did not care to have the man exposed to a longer operation than was necessary, nor did I care to have him die under my hand.

A suggestion, though homely, occurred to me then. One has great trouble in bringing the ends of the gut in apposition, and we do not always have cones of cocoa butter or gelatine at hand to act as lasts to draw the gut over.

A piece of link sausage out of which the meat has been turned and filled with butter or lard makes a good cone or basis to draw the ends of the gut over prior to uniting them. Just before the last stitch is drawn up a tenotome can cut the sausage sack, and the gradual warmth of the body will melt the butter, allowing it to empty itself into the bowel at the seat of suture, thus filling up any little openings made by the needle. The sausage sac may pass out with the fæces.

Water or air will not do to fill the sac with, since a puncture of the needle would let out its contents before one is through with them. One other point before leaving this case, and that is the immense importance of early operation in strangulated hernia.

Were I to gauge the value of time, I would say hours are worth years in inguinal hernia; moments are worth months in femoral.

I believe there are more deaths due to the complacent, let-alone policy engendered by a few recorded cases of recovery when the patient was on the table for operation than can be laid to the door of any surgeon who operates early. Divest your mind of prejudice born in a suppurative age, and instead of being appalled at death-rate due to late interference, fully appreciate the triumphs of other departments of peritoneal surgery, and apply them to herniotomy.

DISCUSSION.

Dr. L. McLane Tiffany thinks the case interesting from two standpoints.

1. The attempt to divide the stricture external to the sac.

2. The formation of an artificial anus.

As to the attempt to divide the stricture external to the sac, this may be good treatment in some very recent cases, but it is questionable in very many others. By this operation the orifice remains patent, and the patient is liable to recurrence of the hernia. In his opinion, the proper treatment in these cases is to open the sac, reduce the hernia, and stitch together the edges of the ring, in short, to attempt radical cure. With our our present antiseptic methods there is but little risk in opening the peritoneum. Resection is doubtless successful in some cases, but he thinks many patients die as a result of shock consequent upon the manipulation of the intestines. Where a portion of the gut is sphacelated, he advocates resection of the gangrenous portion, sewing together side by side the cut ends, and leading them to an artificial anus.

Dr. John Chambers thinks handling the

intestines no doubt gives rise to trouble. He thinks it better, however, to cut down upon a gangrenous gut, relieve the constriction, and let the adhesions, already formed, remain undisturbed. Don't believe in attempting to resect the sphacelation portion.

Dr. Robert Johnson cannot agree with Dr. Chambers, that it is proper to simply cut down upon a gangrenous gut and leave this dead tissue in the wound. Thinks this dead tissue should all be removed.

Dr. John Chambers thinks statistics will show that a second anus formed by nature under the circumstances, is accompanied by less mortality than when an artificial anus is made by the surgeon.

Dr. Randolph Winslow said, for temporary relief he thought Dr. Chambers' plan a good one, but for permanent benefit it is better to make an anus as described by Dr. Tiffany, and subsequently repair the broken gut. This is the plan now adopted by the English surgeons.

Dr. J. H. Branham knows of no English surgeons who advocate this plan of operation.

Dr. Winslow cannot recall the names of the surgeons referred to, but thinks if Dr. Branham will look through the journals for the past twelve months, he will find him correct in his statement.

Dr. S. T. Earle said, if Dr. Winslow would permit him he would say that Treeves is among the most prominent advocates of the operation under discussion.

Dr. Robert W. Johnson then read the notes on his third case.

(To be continued.)

Editorial Department.

Periscope.

The Therapeutic Value of Mountain-Climbing.

Dr. L. Barkan, of Brooklyn, writes as follows (*N. Y. Med. Jour.*):

Although the strengthening and invigorating effect of exercise, and especially of mountain-climbing, is well recognized, yet it would seem not to be superfluous to examine a little more closely this most precious of remedies, which, by the relief it gives from the cares of business, combined with residence in a healthful locality, active respiration of pure air, and drinking of pure water, exerts not only a transitory beneficial effect, but even, in most cases, leads to a permanent cure, and also tends to prevent disease. Among the most active of disinfectant agents belong a good soil and also, in my humble opinion, good air. The more thickly settled a place, the less potent for good are the hygienic influences of the soil and air; and the smaller the settlement, the more active, *ceteris paribus*, are these two factors; they attain their greatest efficacy in elevated regions.

According to Professors Senator and Fluegge, one volume of good sandy soil can render innocuous two hundred and fifty volumes of ordinary sewage; but as regards the disinfecting power of air we are still in the dark. I believe that the oxygen present in pure air is able, probably by means of combustion, to render more or less innocuous the disease germs received into the blood —that is, to act as a disinfectant. Perhaps the therapeutic efficacy of permanganate of potassium lies in the fact that it favors the reception of oxygen by the blood-corpuscles, while the toxic action of strychnine would seem, according to Rossbach, to be due to the fact that it retards this union of the blood-corpuscles with oxygen.

There are floating in the air numberless germs, many of them of a harmful nature, and it would seem possible that the injurious germs which, especially in large places, are received into the human organism, might be rendered innocuous by the oxygen of the air (and, perhaps, also by air-currents acting in a mechanical way), while in stagnant air —as, for example, in a badly ventilated apartment, where the exhalations from the lungs and skin are constantly accumulating —there is less disinfectant action because of the diminished quantity of oxygen. We seek to get rid as quickly as possible of the other excretory products while, strangely enough, the same amount of zeal in disposing of the exhalations—that is, the excretions—of the lungs and skin is comparatively seldom exhibited. And, indeed, thorough and effective ventilation of the living-room is not so readily obtained. As nature purifies the atmosphere partly in an electrochemical way, by means of thunder-storms, and partly in a mechanical way, by means of high winds, so must we, upon occasion, purify the atmosphere of our dwellings by

means of fumigation and the use of disinfectants, but especially by constant ventilation, and sometimes by the production of artificial currents of air. At whatever cost, the air must be thoroughly changed in every corner and crevice of the room. While serving in the Turco-Servian war, I kept the windows in almost every room in my hospital constantly open, even during the night; and I had the satisfaction of observing that, while in other hospitals small-pox and other contagious diseases prevailed, in my hospital they seemed to find no suitable soil for their further development, and, notwithstanding that, from want of room, I was often obliged to put patients suffering from small-pox, typhus, erysipelas, diphtheria, etc., together with other patients in the same ward, these diseases did not spread.

A favorite experiment of mine, and one from which I never saw any but favorable results, was to send patients suffering from grave diseases a distance of six miles to another and more roomy hospital. They were removed even in winter, when the weather was not excessively cold, but were, of course, well wrapped up, and every precaution was observed to prevent them from receiving any injury on the way.

It is well known that not every one exposed to a contagious disease acquires that disease; and may it not be that those escape entirely or suffer from a mild form of the disease who, after exposure, spend a considerable time in the open air? I leave out of consideration the fact that the danger of contagion depends also somewhat upon the position that the visitor occupies when at the sick-bed.

So much as to the value of pure air. It is of especial efficacy in elevated regions, and its good effects are the more evident the higher the climber ascends, and the more muscular effort he puts forth in the ascent. The best inhalation apparatus, baths, and medicaments are of but temporary value if no compensation is made for the loss of vitality and of muscular tone, especially that of the heart and vessels; if the blood stasis in the glands and other organs does not yield to an increased flow of blood in the arteries and veins; if the thinned blood does not become thicker and more rich in albumen; if the accumulating carbonic acid is not expelled by a more plentiful supply of oxygen; if the fat deposited in the body is not more rapidly oxidized; and if the kidneys are not made to act more efficiently. But all these effects are produced, according to Jacobi, Loomis, Voit, Oertel, and other authorities, more certainly and more generally by mountain-climbing than in any other way whatever. After several weeks spent in mountain excursions, the condition of the patient is radically changed for the better. There is an elasticity in the mental processes in place of the former hebetude; will, thought and impulse seem to move on wings; the formerly dull senses are sharpened; the formerly half-closed eyes sparkle, and the flabby cheeks become fuller and rosy; the formerly prominent abdomen is reduced to more seemly dimensions, notwithstanding that food and drink are taken with greater relish, and the chest is expanded. These changes, it is true, are not without their inconveniences to the patient as regards his apparel, for his unmentionables are found to have become too wide around the waist, while his coat, collar, and shirt are too small. The one who was before so heavy and dull now feels as elastic and springy as if the burden of earthly existence had been lifted from his shoulders, and, almost as in his childhood days, he goes running and springing along, and covers a distance of ten or twelve miles a day. He is no longer in the shape of a discontented and surly creature; a parody on man, but fits better in the ranks of other strong and happy beings; he is possessed of a new spirit, the pulse beats more strongly, and the tone of the entire circulatory system is better.

I will now instance a few cases showing the good results obtained by patients whom I have accompanied in various mountain tours in Europe and other parts of the world.

Case 1. J. B., forty years of age, weight 230 pounds. Circumference of the waist, 120 ctm.; of the chest, 116 ctm. The first walk caused him to gasp for breath, so that he was almost snorting. The tired heart, with its faint pulsations, seemed hardly adequate to the task imposed upon it, and the patient was forced to stop every three minutes. On the second day the breathing was a little more easy; instead of the snorting respirations, the breath came in quick panting jerks, as in pneumonia. He was obliged to rest every five minutes. The secretions were increased in amount, and the torpid condition of the bowels was corrected. The distance covered in the walk was lengthened a little each day. At the end of a month, climbing caused but slight acceleration of the respirations, which were almost inaudible; there was only moderate perspiration, and the patient was able to continue for at least a quarter of an hour without stopping to rest; and he could soon climb

for four hours a day, whereas on the first day he could barely continue for a single hour. The cardiac contractions were now full and strong, and the patient had long since lost the feeling of oppression of the chest and dyspnœa. At the end of the trip his weight was 208 pounds, the circumference of the waist 107 ctm., and of the chest 121 ctm.

Case 2. T. R. had suffered from paralysis of the left facial nerve. In 1879, when he was thirty-four years old, he had had another attack, and, although under the best of medical care, his physician would not promise a perfect cure. The treatment had consisted in the application of a strong galvanic current. At the conclusion of his treatment the patient still had had a feeling of numbness in the affected cheek. After an excursion of three weeks' duration, this numbness had entirely disappeared, and there has been no return since that time. On one occasion the patient objected to taking the walk, on account of a severe and painful attack of diarrhœa; but he finally yielded to my advice and went, and two hours later all the symptoms had disappeared.

Case 3. E. F. S., fifty years old, had suffered for thirteen years from rheumatism. At first I let him ride a part of the way and walk a part on level ground. At the end of two weeks he could climb hills. After doing this for a week and a half his rheumatism had permanently disappeared. The patient indulges in this mode of treatment now every summer.

Case 4. C. W., thirty-nine years of age, was plethoric and hypochondriacal, and suffered from hæmorrhoids. An improvement was noticeable at the end of two weeks; and at the expiration of four weeks the hæmorrhoids had entirely disappeared, and the patient began to enjoy life. His weight at the beginning was 211 pounds, at the end of the trip it was 185 pounds; the measurements around the abdomen and chest were 108 ctm. and 104 ctm. respectively at the commencement of the tour, and 98 and 109 ctm. at its termination.

Case 5. H. L., thirty-two years old, was suffering from chronic catarrh of the stomach. There was a noticeable improvement at the end of one week, and after three weeks the stomach was in good condition, and the patient was obliged to observe but little care in his diet. A bronchial catarrh, which had given him constant trouble, was much improved the first day, and had disappeared by the end of the third day. His weight was at the commencement 145 pounds, and at the termination of the trip 160 pounds.

Case 6. L. S., twenty-five years old, suffered from psoriasis. At the end of twenty-four days this had permanently disappeared.

Case 7. J. B., eighteen years of age, had trouble at both apices, and complained of a poor appetite. At the end of five weeks the patient had gained nine pounds in weight and felt very well.

Case 8. Miss A. O., nineteen years old, had chlorosis, amenorrhœa, and suffered from a miserable appetite. After seven days there was a marked improvement, and at the end of two weeks the patient presented the appearance of a healthy girl with an excellent appetite.

Case 9. Mrs. L. P., forty-eight years old, was weak, hysterical, and had not menstruated for two years. At the expiration of eight weeks she was much stronger, had no more hysterical attacks, and menstruation had commenced again.

In organizing parties for mountain-climbing, it is necessary to have everything arranged and to attend to certain preliminary details. Regulations should be established as to the gradual increase in the extent of the daily ascents, the periods for rest, the choice of food, the permission to drink, the regulation of time for stool, the protection of the feet, legs, and nates against chafing and the formation of blisters, the protection of the neck, and finally the selection of the mountain up which the ascent is to be made; these are all points which require careful consideration. The European mountains, where there is a better climate, and, as rule, better paths than are to be found in the mountains of America, are to be preferred. An exception is, however, to be made in favor of the Adirondacks and some other mountains in the Eastern States, which might answer as places for exercise for American youths in search of health. It is necessary to take into consideration the individuality of the patient; and, in order to avoid monotony, which may be wearisome to the patient, it will be advisable to change from one mountain or one locality to another, so that the patient will not be tempted to discontinue the treatment.

The Diagnosis of Uræmia from Apoplexy.

Dr. C. W. Suckling thus writes in the *Brit. Med. Jour.:*

Chauternesse and Tenneson, in the *Revue de Médecine*, November, 1885, relate cases of partial epilepsy and hemiplegia in Bright's disease, which they have, by post-mortem examination, proved to be due to local œdemas of the brain.

I believe that it is not generally known that hemiplegia occurs in uræmia, thus occasionally making the diagnosis between uræmia and apoplexy an extremely difficult one—as in uræmia the treatment must be one of active interference, while in apoplexy the opposite holds good, the diagnosis is of the utmost importance.

I have recently met with two cases similar to those reported by Chauternesse and Tenneson. A man aged 40 was recently admitted into the workhouse infirmary in a comatose condition, with right hemiplegia and without convulsions. The pulse was of high tension, the heart considerably hypertrophied, and there was a trace of albumen in the urine.

All these symptoms were compatible with the diagnosis of cerebral hemorrhage. To my astonishment, he recovered consciousness immediately after being bled, the hemiplegia passing off in a few hours.

During his stay in the infirmary, he had five other attacks, which were always preceded by delirium and restlessness, together with violent convulsion of the right side of the face, right arm and leg, and conjugate deviation of the eyes to the right, giving place to hemiplegia, the eyes then being turned to the left. Each attack was cured by a small bleeding. The urine in this case was free for days from albumen, though it was tested at various periods of the day.

The other case was that of a woman, aged 63, brought in one evening completely comatose. There was right hemiplegia, conjugate deviation of the eyes to the left, dilatation of the right pupil, and abolition of the right conjunctival reflex.

The breathing was of the "Cheyne-Stokes" type, the heart a little enlarged, but the pulse of low tension. Clonic spasm of the facial muscles occurring at short intervals, the case was suspected to be uræmic, though the urine apparently was not albuminous, and I ordered her to be bled. One ounce and a quarter were drawn, and she became conscious almost immediately after.

The next day the hemiplegia had disappeared, but she had sensory aphasia, there being "word-blindness" and "word-deafness." Free purgation was kept up, and within two days she was perfectly well.

On testing the urine by daylight, I found there was a slight trace of albumen present, the quantity of urea being only one per cent., and the average daily quantity of of urine passed being forty ounces. I could discover no casts, and there was no change in the fundus oculi.

In both the above cases the temperature was a little below normal; and in both no history of the onset of the attack could be obtained, the patients being brought in from the street by the police. In the diagnosis of these cases, the occurrence of convulsions is of great assistance. A convulsion occasionally occurs at the onset of apoplexy, but is rarely repeated, while in uræmia convulsions are common, and usually frequently repeated; any elevation of temperature would be strongly in favor of apoplexy. In all cases, when in doubt between apoplexy and uræmia, I should bleed.

Eruptive Eccentricities.

Dr. J. G. Marshall thus writes in the *Lancet:*

Mrs. Q., aged forty-eight, married, living alone, had been a sufferer from chronic rheumatism for several years. She had an attack of facial erysipelas some time back, but could not fix the date. She was subject to occasional severe attacks of neuralgia, for which I could find no visible cause. About two months ago she presented the symptoms of erythema nodosum, and went through the illness in a severe and typical form, the patches being very large and painful, leaving the shins, back of forearms, and inside of thighs covered with livid marks, as if she had undergone a beating. At the end of a fortnight this eruption seemed to have run its course; but the patient still seemed very unwell, and complained of stiffness about the neck and jaws, with continual pain in the head. She maintained that she had been snffering from erysipelas, though she acknowledged that she had not been like it before. Two days after the last crop of erythematons lumps had disappeared, she was seized with erysipelas of the head and face, and had it very severely, with high fever and extensive swelling of the face and neck.

She was for two or three days in a very critical condition, the features being almost obliterated, and the infiltration of the tissues of the neck deep and extensive. One morning when she was getting better she complained of intense itching of the back of the forearms and hands, which on examination presented the unmistakable white "wheals" of urticaria. There was little or no redness of the skin; the eruption was confined to the extensor surface, did not reach above the elbow, and died away in forty-eight hours. There had not been a trace of erysipelatous rash on the body during the attack of that

disorder. A short time ago I congratulated her on getting on so well, when she said that she had another attack of erysipelas at the bend of the elbow. On examination of each elbow-joint, on the flexor side, and nowhere else, I found a patch of typical eczema, the vesicles being perfectly unmistakable, with watery exudation and shiny redness. She had been scratching with her nails, which she had not done before. Fresh patches of eruption appeared at the wrist. Both yielded readily to treatment, and now nothing is left but a little branny desquamation.

The case is such a remarkable one that I think it deserves publication. I have not the smallest doubt as to the several characters of the eruptions, which I observed most carefully. Unfortunately, I am at a disadvantage in being at a distance from any of my own profession, or I should have exhibited the ease. I am quite prepared to see this lady shortly with a fine development of herpes zoster, or exhibiting patches of psoriasis to complete the series. She is of a highly nervous temperament, and occasionally subject to fits of great excitability.

Peculiar Effect of Cocaine.

Dr. J. W. Stickler, of Orange, N. J., reports the following to the *Med. Record:*

"On January 21, 1887, a patient came to me presenting a small cyst in connection with the extensor tendon of the middle finger of the left hand.

"After introducing into the cyst about five drops of a twenty per cent. solution of cocaine, I opened the sac and evacuated its semi-fluid contents. In less than half an hour the finger began to swell, and in less than two hours the swelling was extreme. Very soon systemic disturbance became manifest in the following symptoms: dizziness, headache, pallor of skin, nausea, and diarrhœa. During the first night the patient slept but little.

January 23. Finger swollen, tender to touch, somewhat painful, red and hot, but not œdematous. Same constitutional condition as previous day.

"January 24. Finger has same appearance as on the 23d; no œdema; the hand somewhat swollen and slightly œdematous. Diarrhœa has ceased. Nausea slight when patient sits up or walks. Still complains of dizziness.

"January 25. No change in the appearance of the finger, but the hand is more swollen. No evidence of suppuration. Patient able to sit up without suffering from either nausea or dizziness.

"January 26. The swelling of the finger is somewhat diminished, although it is still tender, and somewhat painful. The general disturbance has disappeared, but the appetite is greatly impaired. After the last date the swelling subsided quite rapidly, so that by the last of the month the use of the joint was regained.

"As has been said by others who have written concerning the effect of cocaine, congestion is of frequent occurrence, but I have witnessed only this one instance of alarming congestion following the hypodermatic use of the drug. I call the condition 'congestion,' because the enlargement of the finger reached its utmost limit in about two hours after the use of the cocaine, and the finger had about the same appearance as would have been produced by constriction of the part with an elastic band.

"The systemic disturbamce was also more pronounced than is usual. I am therefore led to believe that the hypodermatic use of strong solutions of cocaine is attended with considerable risk, unless it is known prior to its employment just how susceptible the patient may be to its influence."

Hyoscine in Kidney Disease.

After relating a case in *The Practitioner*, Dr. Nestor Girard thus concludes his observations on this case:

Hydriodate of hyoscine is a drug which can be used with perfect safety in cases of kidney disease where morphine is inadmissible. It is a drug which may give rest when other sedatives fail.

If used in two-minim doses subcutaneously it may give more satisfaction to the patient than to the attendants, since the unconsciousness may be accompanied by angry and combative delirium; should this occur it will probably be sufficient to diminish the amount employed.

It is very rapid in its action, unconsciousness following in from ten to twenty minutes, and the after-effects are of a soothing character.

Even when delirium is present in a violent form, it is followed by quiet sleep, and the patient being unconscious, is much more refreshed than by a night of short snatches of sleep produced by chloral or bromide, and the result is a marked improvement in both aspect and temper. And lastly, no irritation is produced around the site of injection.

I believe that hydriodate of hyoscine will probably take a firmly established position as a sedative in cases where morphine cannot be employed.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. J. W. McLaughlin, of Austin, Texas, read an article before the American Medical Association, containing his researches on the etiology of Dengue. In the reprint of it before us he gives his reason for believing that this disease is the product of a low organism, and will in time—before another ten years—"be as certainly prevented by inoculation as small-pox now is."

——In a reprinted article on the treatment of vaginismus, Dr. Thomas More Madden finds occasion to differ with Sims' statement that it is an easily curable disease. Mechanical dilatation and stretching the pudic nerve succeed sometimes, but not always. Each case has to be treated on its own merits.

——"Two Obstetrical Heresies" is the title of a reprint by Dr. S. F. Starley, of Tyler, Texas. The author states his opposition to the following two obstetrical canons: "The first is the part that the membranes containing the amniotic fluid and the fœtus play in effecting dilatation of the os uteri in the first stage of labor. The second is the supposed necessity for waiting for their rupture and the escape of the waters before applying the forceps, in every case, without exception."

——The subject of periostitis is discussed in a lecture by Dr. N. Senn, of Milwaukee, Wis., recently reprinted.

——Messrs. Baker & Co., of Dorchester, Mass., manufacturers of chocolate, have issued a neat little volume, entitled "Cocoa and Chocolate, a Short History of their Production and Use, with the Various Methods of Preparing them for Use." It may be had on application to them.

BOOK NOTICES.

Granular Lids and Contagious Ophthalmia. By W. F. Mittendorff, M. D. Pp. 110.

On the Determination of the Necessity for Wearing Glasses. By D. B. St. John Roosa, M. D. Pp. 75. Geo. S. Davis, Detroit, Mich.

Both these volumes are members of the series entitled "The Physician's Leisure Library," published by G. S. Davis. They are offered at the very moderate price of 25 cents each, and are more than worth the money. The subjects are every-day ones, and are treated by the competent authors in a straight-forward, practical manner, very satisfactory to the reader. A half dollar cannot be better invested than in purchasing them.

Tenth Annual Report of the Board of Health of the State of New Jersey for 1886. 8vo., pp, 464. Trenton, 1887.

The Biennial Report of the Board of Health of West Virginia, for 1885, 1886. Pp. 75. Charleston, 1887.

It is gratifying to witness the steady progress which is making toward a completer sanitary supervision of life. The work of State Boards of Health, as illustrated in the publications above mentioned, is such that it cannot fail to be appreciated by the public before many years. It touches so closely on all the dearest interests of social existence, that the time must soon come when it will be awarded commensurate aid.

The reports of the Boards indicate how extensive is the field of public sanitation, and also how earnest are many of the workers in it.

Hand-Book of Materia Medica, Pharmacy and Therapeutics. By Samuel O. L. Potter, M. D., etc. Cloth 8vo., pp. 828. Price, $3.00. Philadelphia: P. Blakiston, Son & Co. 1887.

The firm of Messrs. Blakiston & Co. are issuing a series of manuals of medical science, at the price of $3.00 each, cloth, of which the above is one of the volumes. The author is Professor of Practice in the Cooper Medical College, San Francisco, and has already appeared before the profession in some smaller works. He includes in his survey not merely materia medica, but also the physiological action of drugs, the special therapeutics of disease, official and extemporaneous pharmacy, and minute directions for prescription writing. His aim is to make the young practitioner and the country doctor independent of the drug store, if either wishes to be.

The book cannot be called an original production. It is made up from the current leading treatises on materia medica and practice, and from the author's lecture notes; the selection and arrangement, however, are judicious, and though it were easy to criticize the plan, its execution must be admitted to be excellent. There is an appendix with numerous tables, and a carefully prepared index.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

OPHTHALMOLOGY AND DISEASES OF THE NERVOUS SYSTEM.

The Bowman lecture of J. Hughlings Jackson bearing the above title has just appeared in the *Transactions of the Ophthalmological Society of the United Kingdom*, 1885–86. It is characteristically brilliant and suggestive, more especially to one who has not perused the more exhaustive statement of the author's psychological and neurological philosophy set forth in the famous Croonian lectures of 1884, (published in *Brit. Med. Jour.* of that year). In this year's address the general position taken in the Croonian lectures on the Evolution and Dissolution of the Nervous System is reaffirmed. The "organ of mind" is considered to be "simply a series of sensori-motor centers re-re-representing impressions and movements of all, literally, all parts of the body." The frontal lobes of the brain, preponderatingly motor in character, are the agent of this third stage of abstraction or representation; the middle convolutions, Ferrier's motor region, intermediate the re-re-representative stage; whilst the simple representative phase is given by the nuclei of the cranial nerves and anterior horns of the cord. The whole conception of cerebral function and disease is confessedly based upon the evolution philosophy, set forth particularly in Herbert Spencer's psychology, and derives therefrom a striking reach and substantiality of reasonableness. The relations of ophthalmology and neurology are somewhat discursively touched upon, and one feels that it is the neurologist *par excellence* that speaks, and is paying that half-forced attention to ocular symptoms that his audience and his duty of the hour demands. Despite this, it goes without saying that the allusions are luminous and to the last degree suggestive. First of all, the specialist is justified as a factor in the universal trend of the law of evolution, which, while persistently bringing about differentiation, as absolutely necessitates increased definiteness, increased integration, and increased coöperation. "The neurologist ought at least to be able to suspect hypermetropia as a cause of head-troubles, but only the skilled ophthalmic surgeon can estimate it precisely and correct it accurately." Epilepsy is the illustration used throughout the lecture to exemplify the author's psychology. This affection is held to be of the nature of an excessive discharge in the highest centre, what he has elsewhere called "a physiological fulminate." From these complex centres the discharge proceeds towards the periphery according to

the extent and power of the initial force and the anatomy of neural distribution. Like all other movements, the eye-symptoms, such as the apparent alteration in the size or distance of external objects, colors, ocular movements, etc., are the indirect reflex results arising during epileptic discharges of sensory elements. The coma or "paralysis" consequent upon epilepsy arises from the exhaustion of the lower centres; hence, *inter alia*, the diminutive size of the pupils in this state. The lecturer speaks of the visual centre according to Ferrier, as located in a space supplied by the middle cerebral artery. In Ferrier's last edition, however, Ferrier admits that this centre is "*also*" in the occipital lobes as well as in the angular gyri. That it is pretty certainly delimited to the cunei of the occipital lobes is quite beyond doubt at present. As to optic neuritis and its value as indicating brain tumor, the author is quite decided in the body of the lecture, that operation is only to be advised when optic neuritis is present; but in a post-scriptum note he recants, and gives an instance of successful operation when no neuritis or headache were present. The epileptiform seizures in this case began in the patient's left thumb, and to the uninitiated it seems almost ludicrous to hear the lecturer gravely assert that he advised the excision of "a *part* of the thumb centre," and testify to the patient's complete recovery. From a case where optic neuritis had disappeared under treatment the dictum is adduced and italicized that "*a man with optic neuritis is to be considered as being in imminent danger of death.*"

That the neurologist and ophthalmic surgeon have a common ground is strikingly exemplified in the following excerpt: "It is well known that with destructive lesions of the brachial plexus we have smallness of the pupil on the side of the injury. Ferrier finds that in the monkey, and presumably it is so in the man, the dilator fibres of the iris, contained in the cervical sympathetic are derived from the anterior root of the *second* dorsal nerve. In the monkey the second dorsal sends a communicating branch to the brachial plexus, and so it does in most cases in man. Now the second dorsal root supplies also the intrinsic muscles of the hand. In one case I have observed a small pupil (inability to dilate when shaded) in a case of progressive muscular atrophy at a stage when the hand muscles were almost solely those atrophic."

From the deductions of Ferrier and Yeo that movements of the eyes and head are represented in the frontal lobes, the lecturer adds another proof to the many that seem to meet one everywhere, of the superlatively important rôle of the eye in the development of the intellect. "Ocular movements are the most representative of all movements. Most mentation is carried on in visual perceptions and ideas; and as there is an element of, or symbolizing, shape in all visual perceptions and ideas, there is of necesity a representation of ocular movements in the physical bases of these perceptions and ideas, that is, in the highest centre." G. M. G.

POISONING BY BELLADONNA.

A peculiar and very instructive case of poisoning is reported by Dr. Hermanidez (*Weekblad van het Nederl. Fijdsch. voor Gen.*, 1886, p. 484). In a peasant family consisting of eight persons, shortly after a meal, consisting of codfish, potatoes, and a sauce made of butter, peculiar phenomena of illness developed, which at once indicated intoxication by atropia. As a great number of chickens owned by the peasant had died a week previous under analogous symptoms, and as it was well known that the family had had a bitter dispute and fight with some neighbors, the public prosecutor ordered an examination of the dead chickens, though all the members of the family were sure of not having eaten of the flesh of the chickens. The animal, which was handed to Dr. H. for examination, had been lying in a swamp for over a week. H. found an alkaloid in the flesh, but it was one formed by the process of decomposition—a ptomaine. Besides, he convinced himself by experiments, that chickens can take as much as 150 mgrms. of atropia, and that the animals referred to would have had to have eaten large quantities of the drug to have caused their death. The most careful examination revealed no trace of atropia in the chicken given to H. for analysis, and the family could not have died of the flesh of these birds. Finally, a piece of the codfish was found, and in it considerable quantity of the alkaloid. Further investigations demonstrated the fact, that while the peasant's wife, who is nearly completely deaf, was alone in the house, a neighbor entered, unseen, the kitchen, and emptied an ounce vial containing a two-grain atropia solution, which had been prescribed by his physician for some eye disease, over the codfish—his intention being revenge for some imaginary wrong. Happily a large part of the fluid had been previously used and spilled, otherwise the result would have been a fatal one.

The discovery concerning the criminal was brought about in this way. In Europe it is very difficult for anybody to obtain poison without the prescription of a physician. As soon as the court had been informed of the presence of the deadly alkaloid in the piece of codfish accidentally left over and preserved, they started an inquiry amongst all the physicians and apothecaries in the neighborhood, to find out, whether any of them had written such a prescription or put up the same. No information was thus obtained, but one of the physicians remembered, that half a year previous, the revengeful neighbor had suffered from eye disease and consulted him, and that he advised him to go to the city to be treated by a specialist. When the latter was asked, he admitted having prescribed the atropia-solution, which was put up by an apothecary in the city. On being confronted with the circumstantial evidence, the man admitted his having done the deed, but denied having aimed at the death of the parties.

Notes and Comments.

Syphilis During Pregnancy.

A series of very remarkable clinical observations on syphilis in pregnancy have recently been made by M. Hirigoyen, at the Maternity Hospital in Bordeaux, from which he concludes that, from an obstetric point of view, both abortion and natural labor take place in syphilitic patients exactly as in healthy women. In certain exceptional cases, however, difficulties attributable to syphilis may arise, such as hemorrhage from partial adherence of the placenta, rigidity of the os, etc. Finally, women suffering from primary or secondary syphilitic lesions in the genital organs are rather predisposed to puerperal accidents, and require more attention on the part of the attendant than other women. The following is a summary of the observations, which extended over a period of two years:

1. In the lying-in wards, in Bordeaux, the proportion of syphilitic to other patients was 5 per cent.

2. Five-sixths of them were unmarried.

3. Syphilis in a pregnant woman tends to bring about premature labor.

4. The duration of the disease seemed to have a very decided influence.

5. In eight cases of pregnancy in syphilitic women who had had the disease for one or more years, only two children were born alive, and these were very puny.

6. In twelve cases, in which the mother had contracted the disease during the first four months of pregnancy, the fœtus was in every case still-born.

7. When the mothers had become affected between the fourth and the sixth months of pregnancy, the fœtus died in about half the cases.

8. When syphilis had been contracted during the three last months of gestation, the proportion of living children was a little more than one-half—four out of seven.

9. Out of thirty-three cases of pregnancy in syphilitic women, living children were born in eight.

10. Syphilis may give rise to difficulties during labor, and also to subsequent complications; but this is rare.

11. To be effectual, anti-syphilitic treatment should be administered from the very beginning of pregnancy, and continued throughout. The treatment should be perseveringly carried out, in order to prevent accidents in future pregnancies.

Total Extirpation of the Uterus and Nephrectomy.

Dr. Schmidt, of Cologne, relates in the *Münchener Medizinische Wochenschrift*, No. 33, 1886, a case in which these formidable operations were successfully performed at one sitting. The patient was 49 years old, and had given birth to four children, all still-born, and the menopause had occurred two years previously. For a year she had suffered from severe, irregular uterine hemorrhage. Carcinoma of the cervix, involving the vault of the vagina, was detected. The uterus was removed, but the operation was rendered very difficult by abundant cord-like adhesions between the fundus and the pelvic walls. The peritoneal cavity had to be very widely opened. On careful examination of the extirpated uterus, it was found that an inch of the right ureter had been cut away with that organ. The vagina was plugged with iodoform gauze, and the right kidney was removed through a lumbar incision. The patient made a good recovery. Dr. Schmidt states that the total extirpation of the uterus is quite inadmissible, when it appears at all probable that a ureter is likely to be injured, not that the necessary nephrectomy would greatly increase the risk, but rather because the extirpation of the uterus would be of little service in such a case, as the cancerous infiltration would be extensive, and rapid recurrence would be certain. Yet, when the ureter has been in-

jured he thinks that nephrectomy is preferable to sewing of the proximal end of the ureter to the vaginal walls, as this leads to inflammation and sloughing, and renders nephrectomy necessary later on. In Dr. Schmidt's case it must be noted that the disease had distinctly involved the cellular tissue to the right of the cervix.

The Existence of Pepsine and Trypsine in Urine.

Dr. Vasilevski, at Professor Chudnovski's suggestion, recently undertook some observations on the urine of twenty patients suffering from various diseases, in order to confirm the statements made by a number of authors —Brücke, Grützner, Sahli, Leo, Mya, Belfanti, and others—as to the constant existence of pepsine and trypsine as urinary constituents. He found that in both healthy and diseased states pepsine in greater or less quantity was constantly present. The smallest quantity was found in patients who were badly nourished, the state of nutrition of the body having apparently more influence upon the amount of pepsine in the urine than the nature of the disease. The least quantity of pepsine was found in the urine of a patient with pulmonary phthisis four days before death, and in that of another who suffered from carcinoma of the pylorus. In this case the pepsine was greater in amount when the pylorus was pervious, and less when it was impassable, and the patient vomited matter in a high state of fermentation. A high body temperature appeared to lessen the pepsine. In three cases in which the urine contained albumen, the quantity of pepsine co-existing with it appeared to be much the same as might have been expected from the state of the patient's nutrition if there had been no albuminuria. In regard to trypsine, Dr. Vasilevski was unable to obtain definite results.

The Cold Affusion in Headache.

Sir Robert Christison, in his "Autobiography" (says the *Lancet*), bears emphatic witness to the efficacy of this treatment, citing in particular the case of his own mother, who suffered from headache of a peculiarly persistent character, and who cured herself effectually by the cold douche. It was the favorite remedy of the Romans, as may be inferred from more than one passage in the judicious compilation of Celsus: "Capiti nihil aeque prodest atque aqua frigida" (Nothing is so beneficial to the head as cold water), Lib. i., c. 4. Again (Lib. i., c. 5), when touching on the various inflammatory affections of the head and its cavities, he says: "Usus aquæ frigidæ prodest iis etiam quos assidue lippitudines gravedo, destillationes, tonsillaque male habent" (The cold affusion is of benefit to those also who suffer from chronic ophthalmia, from cold in the head, from catarrh, and from inflamed tonsils). Again, the lassitude and headache induced by the sirocco (*auster*), to which the British resident on the Mediterranean is so subject, and which no amount of acclimatization seems to lessen, has its appropriate remedy in cold water: "Præcipue omnibus eo auxilis utendum est ubi gravius caelum austri reddiderunt" (This remedy is of especial advantage to all when the atmosphere has become heavy by the sirocco), Lib. i., c. 5.

Caffeine in Heart Disease.

The *British and Colonial Druggist* says that a series of investigations into the therapeutics of caffeine citrate have been undertaken by Dr. Otto Seifert (Wurzburg) during the course of last year. He administered it to patients suffering from organic affections of the heart with imperfect compensation. In one case there was chronic nephritis, with generalized œdema. According to Lepine, the daily dose of caffeine should be from one to two grammes. The drug was given in seven cases, sometimes in repeated doses, at others all in one dose. The principal advantage which has been claimed for it is that it quickly improves the action of the heart and regulates the cardiac beats. It is also a diuretic. One to two grammes of caffeine should be given in twenty-four hours; it has no cumulative action; indeed, the speedy elimination of it, and consequently very temporary action constitutes one of its principal drawbacks. In those cases where compensation has been re-established, the action of caffeine may be as prolonged as that of digitalis. The general condition is influenced in a striking manner; disappearance of the palpitations and dyspnœa being, as a rule, rapidly effected.

An Intermittent Form of Meningitis.

Dr. Henoch has described a moderate form of simple, non-tubercular meningitis, characterized by a protracted course and by alternations of exacerbation and improvement (*Centralbl. f. klin. Med.*, February 5th). The onset is sudden, the fever being more or less intense, with frontal headache, sometimes vomiting, and always marked rigidity of the

muscles at the back of the neck, which may sometimes affect the muscles of one or other side. The fever abates, and improvement occurs after one and a-half to two weeks, to be followed by a renewed exacerbation after an interval varying from twenty-four hours to several days, without any apparent cause. These variations may be repeated frequently in the course of the next few weeks, cure resulting in from seven to ten weeks. Cases in which the remissions are not marked usually end fatally, especially when they occur during the first year of life. Treatment appears to have little or no effect on the disease, and its etiology is frequently obscure, although sometimes it seems to depend on some infectious cause. Flexion of the knee-joint, with the thigh at right angles to the trunk, as described by König, is not always present.

Poisoning from a Vaginal Injection of Sublimate.

The *Therapeutic Gazette* publishes the following instructive case, which originally appeared in the *Centralblatt für Gynäkologie*, by Fleischmann, of Prague. A perfectly healthy primipara, aged seventeen, exhibited no symptoms of kidney disease, or of any other complication of pregnancy. To disinfect the vagina before labor, two douches of 1 to 2,000 solution of sublimate were given, one before and one after examination by a midwife. It was noticed that a small amount of bloody mucus was expelled from the vagina after the douches. In a few hours abdominal pain, diarrhœa and a rise of temperature occurred, all the symptoms and lesions of mercurial poisoning developed, nephritis, salivation, and continued diarrhœa, and, after giving birth to a living child, the patient died in coma on the ninth day after the douches were given. The pathological anatomical diagnosis made at the autopsy was "corrosive sublimate intoxication, acute nephritis, dysentery, stomatitis, and pharyngitis in the stage of ulceration, parenchymatous degeneration of heart and liver, lobar and lobular pneumonia bilateral, acute cystitis."

Carbolic Acid in the Treatment of Vomiting, and Painful Dyspepsia.

The *Boston M. and S. Jour.* says that the well-known anæsthetic and analgesic effects of carbolic acid were first utilized in the treatment of vomiting by Dr. Edward Garroway, of England. He found doses of carbolic acid in some suitable vehicle to allay as by magic hysterical vomiting and the vomiting of pregnancy. Drs. Dixon and Beran afterwards employed the same remedy in the same dose for the relief of some forms of painful dyspepsia; the latter associated with it a certain proportion of the *acetum opii* (English black drops).

Recently Pacholier has essaped the combination recommended by Dr. Beran, in obstinate cases of chlorotic vomiting in the vomiting of pregnancy, in gastralgia from dilatation of the stomach, and from anæmic, nervous causes; and he reports remarkable success from this palliative treatment of these affections. His formula is as follows:

℞. Pure deliquescent carbolic acid, 1 part.
English black drops, 3 parts.

Mix. Dose.—Four drops in a little sweetened water three times a day, a few minutes after meals.

The Use of Iodol in Belgium.

Dr. Edouard de Smeth, in a clinical lecture on iodol given at the Hospital of St. Pierre, Brussels, details several cases of syphilis and soft chancres in which iodol proved very useful. In one of these, iodoform had first been used, but had to be abandoned because of the objection made to its smell by the landlord of the hotel in which the patient was staying. The lecturer also mentioned a case of very obstinate varicose ulcers which had been treated with great success by one of his colleagues by an ointment composed of five grammes of iodol in thirty grammes of lard. He says that iodol is prescribed in Belgium by Dr. Coppez in various ophthalmic cases, by Dr. Houzé in tubercular ulceration of the throat, and by Dr. Lebrun in the form of ethereal injections in endometritis, also by others in various affections under the forms of iodol-collodion, iodol-bougies, etc. In addition to the experiences of Belgian surgeons, those of foreign observers were mentioned, especially those of Marcus of Pyrmont, showing by injections of iodol and iodoform in animals that iodol is far less poisonous than iodoform.

Haschisch Purum and Cannabinon.

This is a preparation of cannabis indica prepared by treating the alcoholic extract of Indian hemp with caustic alkali, by which all acid ingredients are solved (*Pharmaceutical Journal*). The brown soft resinoid residue is "pure haschisch," and is composed of the soft resin cannabinon and the alkaloid tetanine. It is insoluble in water, but forms golden-yellow solutions in alcohol, ether, and

chloroform. A third of a grain is said to act as a cerebral stimulant, and a larger dose causes all the symptoms, including sleep, of Indian hemp. The drug should be in a fine state of division, and may be given in pastile form, with powdered cacao or roasted coffee as a vehicle. Tannic acid dissolves out the alkaloid on which the stimulant action depends, whilst the remaining cannabinon has the narcotic property. Cannabinon is triturated with sugar of milk in the strength of 10 per cent. Made up with cocoa or coffee in pastile form, it may be given as a hypnotic, in doses of one half to one grain and a half, especially for hysterical or insane patients, but it is contra-indicated when heart-disease exists.

Catharsis Produced by Hypodermic Medication.

The *Weekly Medical Review* says: "Drs. Dudley and Castle, in a recent communication, express their belief that one or more agents have been found which will produce free catharsis when administered hypodermically. One of these is cathartic acid, an amorphous substance nearly insoluble in water. Experiments were made with it on animals, and some of the results obtained led them to think that when a better knowledge of its solubility and dosage is acquired it will answer the purpose of a catharsis-producing agent when administered under the skin. As there are frequently cases in which a loss of time is sustained by the administration of cathartics by the mouth, and rectal injections fail to answer the purpose, the existence of some method as the above will be recognized as playing an important part in therapeutics."

A Practical Surgical Hint.

Dr. John F. Lockwood, of Batavia, Ill., writes to the *Med. Record* that a young man came into his office, having severed the radial artery in the wrist. His brother, who accompanied him, controlled the hemorrhage from the proximal end by means of pressure while the writer occupied himself with the distal end, and endeavored to seize the bleeding points. He was unable to find these readily, because of the constant oozing of blood which obscured the field of operation, and sponging was of little avail. It then occurred to him to blow away the blood, which he did, and found that by this means he could keep the wound so free that the ends of the arteries were readily found and tied. He says that with a little care there need be no spattering of blood, but that a well-directed stream of air simply clears it all away from the wound.

Aniline in Phthisis.

Dr. Kremjanskij, formerly Professor of Medicine in Charkow, has recently propounded a scheme for destroying the bacilli of phthisis in the living body by saturating the blood with aniline, which, he says, is poisonous, even in very dilute solutions, to the bacilli, but has never been known to kill a human being. Caution must, however, be used, and the inhalation of fresh air, turpentine, anise, and eucalyptus oils, ought also to be used. He suggests that the drug may be introduced into the system by inhalation of atomized aniline several times a day. The matter was discussed at the recent congress of Russian medical practitioners, and, though it of course evoked a considerable amount of unfavorable criticism, a commission was appointed to watch the carrying out of the plan by Prof. Kremjanskij, in one of the Moscow clinics.

An Explosive Mixture.

Signor A. Cavazzi, according to the *Gazetta Chimica*, has well nigh destroyed his pharmaceutical laboratory, and, indeed, narrowly escaped with his life, by heating together some hypophosphite of sodium and nitrate of sodium. The result might have been foreseen. Equal parts of these salts heated in a crucible explode with the utmost violence. We understand, says this magazine, that this chemist intended to test the purity of a supply of hypophosphite recently imported for pharmaceutical purposes, and with the view of oxidizing the compound in order to estimate the hypophosphorous acid as phosphoric acid, he heated it with nitrate of sodium, with the above-mentioned terrible result.

Vaseline for Hypodermic Medication.

This method of hypodermic medication is extending, especially in France, where it is advocated by M. Meunier, of Lyons, as a vehicle for the introduction of active principles into the system. It is contended that vaseline is absolutely harmless to the tissues, and may be employed in large doses without causing accidents. But the vaseline must be perfectly pure. Pure vaseline treated with warm sulphuric acid does not blacken, but any impure specimen would. Eucalyptol has been thus employed in phthisis, and

turpentine in sciatica. Iodoform, phenol, iodine, and camphor may be injected in the strength of 1 per cent., and thymol in ½ per cent., or menthol 10 per cent.

Iodoform in Heart Disease.

M. Testa has employed iodoform in cases of organic lesion of the valves. The administration of small doses of iodoform (seven centigrammes—about a grain—in four pilules, one to be taken every two hours) rapidly dissipated the functional derangements dependent on the valvular disease. The experimental results obtained in dogs completely concur with those furnished by clinical experimentation in demonstrating that in dogs iodoform retards the cardiac contractions, and this delay increases the total duration of each cardiac cycle, and also the efficiency of the systole.

Rhus Aromatica for Nocturnal Enuresis.

A fluid extract has been sent into the market by Parke, Davis & Co. It is prepared from the cortex of the root of the rhus aromatica, sweet sumac. It acts on the plain muscular tissue of the bladder, uterus, and rectum, and may be employed to check hemorrhages in these situations. Atonic dyspepsia is said to have been relieved by it. Dr. Unna, after a trial of three years, believes the extract to be very efficacious in the nocturnal enuresis in children. Five drops may be given morning and evening to a boy two years old, and ten-drop doses to children of six.

Salicylate of Soda in Gonorrhœa.

Dr. Avsitidiski recommends salicylate of soda in gonorrhœa; the quantity he gives is thirty grains a day dissolved in linseed-tea. The way in which this acts is by being eliminated by the urine, and thus washing out the urethra with an antiseptic solution. Dr. Avsitidiski tried the effect of a 2 per cent. salicylate of soda solution as an injection, and found that it acted similarly to a solution of boracic acid of the same strength, rapidly changing the puriform secretion to one of a mucous character.

Excision of Chancres.

Dr. Andronico claims to have entirely eradicated the syphilitic virus in four cases by excising the primary chancre. He believes that if the sore is situated in a locality such as the nymphæ or the prepuce, where excision is possible, and if the operation is performed within forty-eight hours, or at the very latest three days, from the first appearance of the chancre, success may be hoped for. The excision is, he says, contra-indicated if a longer time than this has elapsed, or if the glands are enlarged.

Bicarbonate of Soda in Tonsillitis.

The treatment of tonsillitis by frequent local applications of carbonate of soda, which has been practiced and recommended by Dr. D. Juan Giné, has been put to a series of tests by another Spanish physician, Dr. D. Rovira y Olive, who deduces from them the opinion that, though it is often beneficial in cases where the parenchyma of the tonsil is affected, it is of much less value than many other applications in cases which are merely superficial and catarrhal.

Sulphur in Chlorosis.

Dr. Paul Strübing and Dr. Hugo Schulz, of Greifswald, state that in a certain class of cases of chlorosis, in which iron and arsenic fail, the continuous use of sulphur is efficacious. In those cases, however, in which there is a catarrhal condition of the digestive tract, it should not be used.

Prescription for Asthma.

Dr. Cazenave de la Roche has found iodide of potassium combined with cow's milk a very efficient remedy for asthma. It should be given as follows: Distilled water, 150 grammes; iodide of potassium, 8 grammes. One tablespoonful of the solution in a cup of milk twice a day.

Correspondence.

A Case of Gleet.

Eds. Med. and Surg. Reporter:

About two months ago a sailor consulted me about a gleety discharge from the penis, following gonorrhœa of five months duration, stating that he had received medical treatment both in this city and in Baltimore, consequently having used numerous remedies, without any perceptible benefit.

Feeling confident the man had a stricture, I began to get my instruments ready for an urethral exploration; this he cut short, however, by refusing to allow instrumentation. I afterwards ordered him potassii bromidum for his painful nocturnal erections, and an

ordinary astringent injection, which he used for a couple of weeks without any diminution in the discharge. In the meantime, while reading the REPORTER, I saw the report of a case of gleet cured by the weak alkaline treatment, *i. e.*, a 2 per cent. solution, of sodii bicarbonas. I ordered this, and to my surprise and entire satisfaction, the discharge ceased. One swallow does not make a summer, nor one cure a specific; but it sometimes makes a practice.

J. NEELY RHOADS, M. D.,
Asst. Gynæcol. Depart., Jeff. Hospital.

NEWS AND MISCELLANY.

Leprosy in Norway.

Dr. Herman Mynter, in the *Western Medical Press*, gives an interesting account of a visit to St. Jurgens, the great hospital for lepers in Norway. Regarding the prevalence of this disease he writes: "While in the middle ages the gallows were erected outside walls of every city to hang every leper who dared to enter, large hospitals are now maintained to take care of these unhappy creatures. A new law has lately entered into force in Norway by which the government has the power to force all lepers into the hospitals, but the opinions about its necessity seem to be divided so far. Leprosy has for years been on the decrease in Norway, from 2,113 cases in 1856, to 1,630 in 1879; possibly on account of the greater civilization and the better knowledge in the population of the disease and of the necessity of its early treatment, possibly on account of the isolation of the infected. The people commence to understand that the earlier the treatment is commenced the better is the prospect of recovery, or, at any rate, such an amelioration of the symptoms that it may be called recovery till a relapse occurs."

Secretary Bayard at Work.

Mr. Bayard is a very hard and constant worker. He goes down to his office every morning at 9, and he seldom leaves for home before 5 in the afternoon. In the middle of the day he sends the messenger out to Ward's dairy for a glass of milk and a biscuit. That is the only meal he takes between morning breakfast and evening dinner. He hardly ever laughs and never really cracks a joke. When he talks it is always with an air of restraint and responsibility. What he prides himself on most is his superiority to other men in being better acquainted with books.

Secretary Bayard is not one of those who, like Fairchild, the assistant Secretary of the Treasury, always put on full dress to dine. When he dines out or when he has guests at home, he dresses in swallow-tail, but for his ordinary evening at home he dons a short quilted jacket, which is both warm and comfortable and neat. Bismarck is Bayard's favorite statesman, and photographs of Bismarck are set up on the mantel and all around the front parlor of Mr. Bayard's mansion.

The International Congress.

Among the list of gentlemen announced by Dr. J. B. Hamilton as intending to be present at the International Congress, we find among surgeons: Mr. T. Bryant, Mr. C. Heath, and Mr. Jonathan Hutchinson, of England. Among gynecologists and obstetricians: Mr. Lawson Tait, of England; Professor Gustav Braun, of Vienna; Professor Hegar, of Freiburg; J. Amédée Doleris, of Paris. Among neurologists and alienists: Drs. J. Althaus, G. H. Savage, D. Hack Tuke, D. Ferrier, H. C. Bastian, Sir J. C. Brown, William J. Mickle; A. Eulenburg, of Berlin. Among dermatologists: Dr. George Thin, of London; Hans von Hebra, Neumann and Kaposi, of Vienna; P. E. Unna, of Berlin. Among general physicians: Drs. B. W. Richardson, Charles West, Eustace Smith, George Johnson, Sir E. Sieveking, N. T. H. Waters, J. S. Bristowe, Pye-Smith, of England; Professor Dujardin-Beaumetz, of Paris; Drs. Lewin, Gusserow, and Veit, of Berlin. Chiari, of Vienna, is also down as intending to be present.

Earthquakes.

With regard to the injuries and deaths from surprise, or shock that have been produced by these commotions in the South of France, as well as to their phenomena generally, the following extract from Prof. Huxley's paper, "Scientific and Pseudo-Scientific Realism," in the *Nineteenth Century* for February, will help to remove some of the misconceptions that invest them: "It is, he says, to say the least, highly probable that this earth is a mass of extremely hot matter, invested by a cooled crust, through which the hot interior still continues to cool, though with extreme slowness. It is no less probable that the faults and dislocations, the foldings and fractures everywhere visible in the stratified crust, its large and slow move-

ments through miles of elevation and depression, and its small and rapid movements which give rise to innumerable perceived and unperceived earthquakes which are constantly occurring, are due to the shrinkage of the crust on its cooling and contracting nucleus."

His Associates "Settled it."

A distinguished literary man of Oakland, says the *San Francisco Post*, stood up in the police court to answer to the usual charge of vagrancy. "I object, your Honor," he said with dignity, "to this persecution of gentlemen who follow the profession of letters, and ——" "I understand," interrupted the judge, "that you were found sleeping under a doorstep, that you have no visible means of support, and that you have been seen under the influence of liquor." "What of it?" cried the prisoner. "Though I am as poor as Richard Savage, when he made his bed in the ashes of a glass factory; as drunken as Dick Steele, who was full nine-tenths of his time; as ragged as Goldsmith when he was on his fiddling tour; as immoral as Byron; as dirty as Sam Johnson; as——" "There, there!" cried his Honor, impatiently, "I've no doubt your associates are a disreputable lot, and I shall deal with you in such a manner as to cause them to give Oakland a wide berth. Sixty days with hard labor. Mr. Clerk, furnish the constable with the names of the vagabonds mentioned by the prisoner."

Insane Chinamen in the United States.

Dr. Wilkins, of the Asylum for the Insane at Napa, California, speaking at the last annual meeting of medical superintendents of American asylums, (*American Journal of Insanity*) said that there were about a hundred insane Chinamen in California. Referring to a belief that there were no insane people in China, he stated that he had been told by some of the Chinese who speak English that when a man becomes insane in China he is put in confinement, and is left alone and dies. In his experience the proportion of Chinese who become insane is not so great as that of other nationalities. They eat rice and unstimulating food, and are less liable to be influenced by the excitements, speculations, and similar causes that serve to bring on insanity amongst others. There was, he said, nothimg peculiar in the forms of insanity prevalent amongst the Chinese. They were affected with melancholia, mania, and dementia. Three cases of derangement amongst Chinese occurred during one of Moody and Sankey's revival campaigns.

Prosecuted for Skin-Grafting.

An extraordinary case of prosecution and persecution has recently occurred in the Atlanta, Ga., courts (*Atlanta Med. and Surg. Journal*). On August 30, 1886, in the presence of Drs. Hardon, Westmoreland, and Howell, Dr. Henry Wile, of that city, proposed to a boy of thirteen years to submit to the removal of some small skin-grafts from his arm to be placed upon an extensive ulcerated surface on the head of his cousin, a little girl somewhat younger, whom he had accompanied to the office. The boy readily consented, and minute grafts were excised without causing him any inconvenience. In the afternoon of the same day the father of the boy went to the office and charged Dr. Wile with having cut "his son's arm to pieces." He subsequently swore out a warrant charging him with assault and battery. Upon trial the case was promptly decided in favor of Dr. Wile.

Medical Degrees for London Students.

A large meeting of the students of the London Hospital was recently held to discuss the scheme for providing medical degrees for London students. Dr. Langdon Down, in the chair, was supported by Mr. Treves, Dr. Francis Warner, and Mr. Munro Scott (Warden). Mr. F. Treves proposed, and Mr. J. Moore seconded, "That a committee be formed to draw up a petition to the Royal Colleges, praying that they use their best endeavors to obtain the power of granting a degree in medicine, and that this committee take such steps as they may think fit to support this petition." Dr. Warner spoke in support of the proposition, which was carried unanimously, Messrs. H. Smith, Watts, Moore, Taylor, and Raynre were elected on the committee, the latter to act as secretary. The meeting was enthusiastic throughout.

An International Congress on Cremation.

An international congress of societies and persons interested in cremation is announced to take place at Milan in September of this year. The programme of the Congress comprises—

1. A general statement of the progress of cremation among different nations.

2. A proposal for constituting an international league of cremation societies.

3. A proposal for international legislation, regulating the removal of bodies from one country to another, and the methods of cremation and conservation of the ashes, from the point of view of public hygiene and legal medicine.

There will be an exhibition of models, plans and designs, books, etc., relating to and bearing on cremation.

A Babe Weighing Just One Pound.

A Lexington (Ind.) special to the New York *World* says:

"Utica, Clark county, a few miles south of here, numbers among its inhabitants probably the smallest baby in the world. It was born on Friday to the wife of Raymond Ferguson, a farmer, and it weighs just sixteen ounces. It is well formed and in very good health. The arms of the little stranger are just three inches long, while its legs measure four inches. Dr. Williams, the attending physician, says it will survive if nothing unforeseen happens. The mother and father of the midget each weigh over 150 pounds, and it is in the best of health."

Cleaning Hair-Brushes with Ammonia.

The best way in which to clean hair-brushes, says the *Popular Science News*, is with spirit of ammonia, as its effect is immediate. No rubbing is required, and cold water can be used just as successfully as warm. Take a teaspoonful of ammonia to a quart of water, dip the hair part of the brush without wetting the ivory, and in a moment the grease is removed; then rinse in cold water, shake well, and dry in the air, but not in the sun. Soda and soap soften the bristles, and invariably turn ivory yellow.

Vaccination in Africa.

Archdeacon Farrar, of Magila, writing frnm East Africa, says: "We have just saved the whole district of Magila from an invasion of small-pox, vaccinating everybody, at the rate of about fifty a day, until all have been vaccinated; so that while other districts have snffered considerably around us, there has not been a single case of small-pox in the Magila district, with its hundreds of villages, and thousands of people. This, of course, has commended our medical science to the people, and they come in numbers."

An Expensive Set of False Teeth.

Dr. Evans, the American dentist in Paris, made a set of teeth for an English lady, the ivories being carefully chosen from the mouths of twenty Breton girls, who submitted to the extraction for a pecuniary compensation. Shortly after the set was delivered, the lady traveled to Mentone, and was aroused from her bed by the recent earthquake. She is now back in Paris with sunken-in lips, having forgotten her teeth in the escape from the shaking Italian hotel. A fresh lot of peasant girls with sound teeth are now wanted.

New Hospital for Madrid.

El Siglo Médico states that the plans of the new hospital of San Juan de Dios, which is about to be erected by the corporation of Madrid, are most complete. The number of beds provided for is 644. The building is to be in ten pavilions, constructed of brick and iron on the Tollet system, and separated from one another. It is expected that the building will not be completed for four years.

Ferdinand Ward as a Laundryman.

Ferdinand Ward is the most cheerful man in Sing-Sing (says the *New York Sun*). "The only fault I can find," he said, "is with the food. I haven't got used to that yet, and I'm afraid I never shall get used to it. I am working in the laundry, and I tell you I'm a daisy handling shirts. I just sort the shirts out and do them up in packages of six, and I never make a mistake in the figures."

Vaccination against Snake-bites.

Professor Sewell, at the University of Michigan, Ann Arbor, has been carrying out some experiments in Pasteurization, taking for his subject the virus from the sacs of rattlesnakes. By attenuation and cultivation he has succeeded in protecting pigeons and rabbits by inoculation, so that they will withstand inoculation of five or six times the strength of uninoculated pigeons or rabbits.

The Wakley Convalescent Home.

The *Brit. Med. Journal* announces that the late Dr. Wakley bequeathed to the University College, of London, his residence at Longcross, together with eight acres of land, for the purposes of a convalescent home for patients from the hospital, as a memorial of his father, the founder of the *Lancet;* also $5,000 to be expended in the maintenance of the home, at the rate of $1,000 a year.

Trichinæ in Beef.

In his earlier years, the late Professor E. L. Youmans was very fond of rare roast beef; but on one occasion Professor Agassiz told him that trichinæ were as liable to be found in beef as in pork, and that the only way to avoid the risk of eating them was to have one's meat thoroughly cooked. Always afterwards Professor Youmans insisted upon having his beef "well done."

Disinfecting Bank Notes.

About $200,000 worth of one and two dollar Dominion notes were disinfected by the City Health Officer at Montreal recently. They had been called in by a local bank during the small-pox epidemic, and the Government officers declined to handle them unless they were first disinfected.

Death of Professor Beclard.

M. Béclard, dean of the Paris Medical Faculty, and Professor of Physiology, died on February 9, aged 70. Pneumonia was the cause of death. M. Béclard wrote a physiological treatise, which has long served as a text-book for students, and still holds its own among its younger rivals.

A Lively Death.

An oysterman whose "saloon" used to be on Maine street was the slowest man in the State. One day he died, and soon after a citizen said to Erastus, the oysterman's son: "Erastus, your father died rather sudden, didn't he?" "Well, yes," said Erastus, "sudden for him."

They Will Have to Pay Them All the Same.

Last summer men went through some New England towns leaving trial bottles of medicine, not to be paid for unless used. Recipients were asked only for a written acknowledgment. Several now find in the hands of third parties notes for $25, bearing their signature.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED MARCH 12, 1887.

Banks, C. E., Passed Assistant Surgeon. To proceed to Chicago, Illinois, and assume temporary charge of the Service, March 10, 1887.

Killed by the Receipt of a Pension Draft.

A colored woman near Oxford, Pa., recently received a draft from the Government for $3600 back-pay and pension for her husband, who died in the army. When the paper was put into her hands, she became so excited that she died suddeely.

Died from Diphtheria.

Dr. E. L. Andrews, a young physician of West Farms, N. Y., died last week of diphtheria contracted from a patient.

Items.

—Dr. Birdsall has been awarded a medal at the fair of the American Institute for his hitching strap.

—A 13-year-old girl, living in Jersey City, suffered last week with toothache, and one side of her face became swollen. The other night the abscess broke, and she bled to death before assistance arrived.

—Mlle. Magnier, the French actress, and four other ladies, paid $40 a day for shelter in an old omnibus in Mentone during the earthquake. A hackney coachman confessed to receiving $400 for a single night's use of his cab.

—A young man living in Ritchie county, West Va., was taken sick with measles. His grandmother, anxious to effect a speedy cure, placed him between two ticks of feathers, with hot stones at his feet and a live sheep alongside of him. He died soon afterwards.

—Pension Doctor—What battle were you in? Pension Fraud—Bull Run. Pension Doctor—Were you wounded there? Pension Fraud—I would have been if I had waited. Pension Doctor—For what do you claim a pension? Pension Fraud—For loss of wind.

—A young lady of Glenmeyer, Canada, was knitting the other day, and thoughtlessly put the point of her needle in her ear. It went further than she expected and touched the tympanum, and as it did so she started with the pain, and the needle pierced the tympanum, destroying the hearing of that ear.

—Arrangements have been made for holding this year a hygienic exhibition at Warsaw. The exhibition will be divided into five groups, comprising respectively the hygiene of food, of dress, of dwellings, of schools, work-shops, and hospitals, and, finally, statistics and meteorology. The opening is fixed for May 15, the closing for July 1.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1054-1556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant. Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

Original Department.

Communications.

A COUNTRY DOCTOR'S OBSTETRIC RECORD.

BY G. LAW, M. D.,

Of Greeley, Colorado.

May 19, 1872. Mrs. C., primipara. Called in consultation. Medical attendant had tried to apply forceps, but had not yet succeeded, for what reason I do not know, as the head was resting on the perineum. We gave ten grains of quinine in a little whisky and hot water. I then placed my hands on the patient's abdomen and manipulated the uterus during the pains, much in the manner since recommended by Credé for expression of the placenta. Result, a living child born in a few minutes. Recovery normal.

July 24, 1872. Mrs. M., IIpara. Vertex; normal in every respect.

October 4, 1872. S.; very small woman; primipara. Vertex; duration less than one hour. Male; weight seven pounds. Mother had mastitis ultimately; had to lance one breast.

October 12, 1872. Mrs. M., VIIpara. Vertex; normal; duration, two hours.

November 26, 1872. Mrs. DeV. Vertex; normal.

February 8, 1873. Mrs. H., aged thirty-nine, primipara, found in the care of a midwife; had been in labor near thirty hours. Found vertex presenting and almost resting on perineum; woman much exhausted; could scarcely be said to be having pains, uterine contractions had grown so feeble and far apart. Gave whisky and fluid extract ergot and applied forceps and delivered a large male child, alive and hearty, and slightly lacerated the perineum of the mother. Country doctors were not then generally careful to sew up small rents, and this was small in this structure, and I did not. The midwife sounded my infamy far and wide in that neighborhood for tearing my patient (or hers) "wide open" with my instruments, and I have done no obstetric work in that section since. Mother made a good recovery.

February 8, 1873. Same day, Mrs. T., aged nineteen, primipara, weight about 100 pounds. Vertex. Second stage became very tedious; patient's strength evidently failing. Fearing undue injury to her structures from the head lying so long wedged in the lower strait, I put on the forceps and delivered, alive, a boy that weighed fully twelve pounds. Placenta came in due time and uterus properly contracted. However, as I was about to leave the house I observed the patient suddenly turn pale and gasp. A quick examination revealed the cause—the most profuse and alarming flooding I ever witnessed either before or since. I was appalled. In an instant I remembered a pail of ice water standing in the shed-kitchen that I had passed through during the night. The nurse was in the next room washing the baby. I opened the door, seized the pail of ice-cold water, snatched the covering off the patient, and dashed the pailful of water on her abdomen. The flooding ceased instantly. I then gave ergot, fluid extract, in a teaspoonful dose: followed it soon with one-half ounce of whisky in hot water, put on a dry bandage, got her on a dry bed, and had no further trouble from the flooding, and the infinite satisfaction of seeing my patient

make as good a getting-up as could be wished.

May 1, 1873, Mrs. R., IVpara, rode twenty miles to this case, and normal in every respect. Patient lived in a sod house; nearest neighbor six miles off, and that neighbor an Indian squaw, the wife of a white man.

June 6, 1873. Mrs. S., primipara; vertex; very tedious second stage; finally delivered with forceps; good normal recovery.

June 12, 1873. Mrs. T., primipara and normal.

July 22, 1873. Mrs. P. IIpara; vertex; normal.

August 28, 1873. Mrs. A., IIIpara; vertex normal.

September 8, 1873. Mrs. W.; vertex; normal; mastitis; breasts lanced; child raised on bottle.

September 8, 1873. Mrs. R., III; vertex; normal in all respects.

September 25, 1873. Mrs. M.; vertex; labor normal; child male, very large; worst case of ophthalmia neonatorum I ever saw; treated with argent. nitras; perfect recovery. Mother had a very extensive prolapsus ani and prostatitis; returned the enormous protrusion under chloroform, tied in a not very well known instrument called a hemorrhodian by its inventor, and kept a stream of ice-water running through the instrument most of the time for four days. This gave great relief, at once effectually subduing the inflammation. This patient has had no trouble since from anal diseases.

October, 1873. Mrs. D.; short labor; twins; first one male, vertex; second, female, breech; both living; recovery normal in every respect. Mother only had milk enough for one; raised the other on bottle.

November 4, 1873. Mrs. L.; vertex; labor and getting up normal.

November 10, 1873. Mrs. B.; vertex; normal.

February 14, 1874. Mrs. B., primipara; vertex; labor short; child male, large; normal recovery.

March 7, 1874. Mrs. B., primipara; child male; vertex; normal.

April 4, 1874. Mrs. M., IIpara; vertex; very lingering second stage; forceps; alive; mother got up well in the usual time.

September 8, 1874. Mrs. N., IIpara; vertex; male; labor short; quick and normal recovery.

September 12, 1874. Mrs. N.; vertex; normal.

October 22, 1874. Mrs. H., primipara; vertex; normal.

December 11, 1874. Mrs. G.; vertex; normal; female; size, large.

March 17, 1873. Mrs. E.; vertex; normal.

March 25, 1875; vertex; normal.

April 28, 1875. Mrs. V.; vertex; normal.

May 4, 1875. Mrs. S.; vertex; child, 7 months, born alive, but died in a few days; mother's recovery normal.

May 10, 1875. Mrs. I.; vertex; normal; labor short.

May 14, 1875; vertex; normal.

May 17, 1875. Mrs. N.; breech; born alive, and followed by a mummified twin that had evidently developed to about the fourth month, died, and by the subsequent growth of its living mate became flattened out as if placed under a press; all parts of its body showed this flattening in a marked degree. The mother had noticed nothing unusual during her period of utero-gestation. She had already borne eight children. The family had always been very poor, and she had worked very hard all her life. Still she was a woman of quite fair intelligence, and would likely have noticed anything unusual if it had occurred. She made a good recovery. Placenta of shriveled ovum likewise mummified—dried.

June 22, 1875. Mrs. F., primipara; free presentation; anterior; forceps; did not tear perineum; child living; mother made a quick and good recovery.

July 10, 1875. Mrs. W., IIIpara; vertex; recovered in usual time.

August 11, 1875. Mrs. C., IVpara; vertex; recovery normal.

September 13, 1875. Mrs. W., primipara; vertex; normal.

October 19, 1875. Mrs. W., IIpara; vertex; lingering second stage; patient's strength obviously failing; forceps; child male, very large, with fontanelles almost closed; alive and hearty; mother's recovery normal; no injury to perineum.

November 2, 1875. Mrs. N., VIpara; vertex; normal.

November 11, 1875. Mrs. W.; vertex; normal.

January 15, 1876. Mrs. W.; vertex; normal.

January 31. Mrs. G.; lived eight miles in the country; child born an hour before I arrived; placenta still retained; flooding until blood had run through or off the bed and stood in pools of frightful size on the bare floor of the cold hovel in which she lived. Gave a teaspoonful fl. ext. ergot; removed placenta, which was found lying in the vagina; passed my hand, and turned immense clots out of the flaccid uterus, and

had the satisfaction of finding it contract firmly and the flooding cease. The patient made a quick and good recovery.

February 4, 1876. Mrs. Q., IIIpara. Vertex; labor short; recovery normal.

February 20, 1876. Mrs. B., IIpara. Vertex normal.

March 6, 1876. Mrs. S. Vertex; normal.

March 16, 1876. Mrs. S., IIIpara. Vertex; normal.

March 21, 1876. Mrs. A. Vertex; normal.

April 6, 1876. Mrs. W., primipara. Vertex; duration thirty hours (twenty-five miles from town); finally put on forceps and was then two hours effecting a delivery. Child alive; weight full twelve pounds. Mother's pelvis of the decided masculine type; perineum uninjured. I have always made it a point to deliver slowly with forceps unless there is some over-mastering reason why I should hurry; generally slip them off when the perineum commences to bulge. Mrs. W. made a good recovery. I have attended her twice since—once using the forceps. Her first boy is now a fine lad.

April 9, 1876. Mrs. H. Vertex; normal.

April 11, 1876. Mrs. D. Child born when I arrived. Uterus contracted on placenta; had to pass hand to remove it. Recovery normal.

May 27, 1876. Mrs. G., primipara. Vertex; labor short and sharp. There is much being said about septic troubles, puerperal fever, etc., in the literature of the profession about this time—locally reinforced by a number of cases that had occurred in our own town under the care of my neighbor, Dr. ——. To some of these I had been called in consultation. The local alarm was great—amounting to almost a panic. Our learned city confréres were recommending hot carbolized vaginal douches as prophylactic and curative measures. My patient manifested some rise of temperature on my first visit and an alarmed and perturbed manner. I considered hers a case upon which to try the douching—hot carbolized water—and gave it myself, and know I did not introduce the nozzle of the syringe into the uterus, but nevertheless the liquid did get there, probably, for my patient had a most agonizing uterine colic, necessitating a hypodermic of morphia before I could leave the house. Nevertheless, she had a good getting up in the usual time. But I was not called as her obstetrician again until last summer—a period of about ten years—she, in the meantime, having to call some one to that service once every two years.

June 25, 1876. Mrs. N., primapara; lived twelve miles out in the country. Vertex. Nothing noteworthy as to the character of the labor. Saw and delivered her.

June 30. Milk established; lochia about ceased; temperature normal; bowels in good condition; appetite good; considered her safe.

Was recalled on the 3d of July. Found her with a high temperature; very sore abdomen, but not in much pain; milk suppressed.

History.—The weather was hot and the house small and uncomfortable, containing only three rooms; in one of these the cooking had to be done for her husband and two hired men working on the farm. To escape the heat, she took a comforter and went out under the shade of a tree, on ground damp from the contiguity of an irrigating ditch, spread it, and lay down on it and went to sleep. Awakened at the end of two hours in a chill, and sent for me. When I arrived, the chill had been succeeded by the condition above noted.

The case proved one of extensive peritonitis.

Thursday, July 6. Counsel was called. The abdomen was enormously distended with gas, which, as the woman seemed almost, if not quite, moribund, we drew off with an aspirator needle, finding it, evidently, in the peritoneal cavity—not in the lumen of the intestines. She scarcely complained of pain from first to last. Died on Friday night, July 7.

This was the first death to occur in my individual practice from or growing out of childbirth during the whole period in which I had been in civil practice—being ten full years, five of these years embracing a larger practice than the five narrated in this sketch. But of these first years I have preserved no written memoranda that is available. They were done in a country town in Michigan, in connection with an old and excellent practitioner for partner. Several interesting things happened that I would like to narrate if I had any written data. Nothing but careful notes can have any scientific weight with any save myself; hence I forbear.

August 10, 1875. Mrs. W., a feeble consumptive child, scarcely seven months; vertex; easy labor; mother did astonishingly well, and we kept the child alive for five months *on bottle-feeding.* It finally died from an attack of catarrhal pneumonia.

August 15, 1876. Mrs. E., primipara; vertex; normal.

September 1, 1876. Mrs. C., primipara; vertex; normal.

September 8, 1876. Mrs. N., VIIpara; vertex; normal.

September 21, 1876. Mrs. M., IIIpara; vertex; on the sixth developed metritis; dismissed well fourteen days after, twenty days from confinement.

October 14, 1875. Mrs. I., primipara; vertex; easy, getting up excellent; child had talipes varus of left foot.

October 24, 1875. Mrs. A., VIIpara; vertex; normal, although a Colorado cured consumptive.

October 21, 1875. Mrs. T.; vertex; labor easy followed by a moderate metritis, that yield'ed in twelve days completely.

December 7, 1876. Mrs. N., VIpara; vertex; labor easy; metritis of ten days duration; final recovery good.

February 26, 1877. Mrs. W., primipara; vertex; labor short, normal.

March 9, 1877. Mrs. N.; vertex; normal.

April 19, 1877; Mrs. W., twins, boy and girl; boy vertex, girl breech; boy large for twins, eight pounds, girl five; amniotic fluid enormous; patient in a very debilitated condition; albumen in the urine; but finally made a good recovery, and raised both her children.

May 8, 1877. Mrs. W.; vertex; labor tedious; flooding severe, followed by some metritis, but eventually made good recovery.

May 22. Mrs. D.; vertex; normal.

June 26, 1877. Child born before I arrived; placenta embraced in a contracted uterus; hand passed and removed; recovery normal.

July 19, 1877. Mrs. J., primipara; vertex; duration 19 hours; female; normal.

August 5, 1877. vertex; duration 10 hours; male; normal.

August 28, 1877. Vertex; male; normal.

September 18, 1877. Mrs. R.; vertex; male; normal.

September 19, 1877. Mrs. P., primipara; weight (mother) 90 pounds; labor tedious—30 hours; no instrumentation; badly lacerated cervix was discovered two months afterwards, on making a speculum examination; to learn why she had not ceased flowing.

September 24, 1877. Mrs. W., IIIpara; short and sharp labor; boy; large; vertex; recovery normal.

September 27, 1877. Mrs. W., primipara; called in consultation after patient had been in labor twenty hours; breech presentation, *which her medical attendant had not discovered;* complete dilatation of uterine mouth; evidently a large child; pelvis of the so-called male type. Medical attendant was an old man; said he was so physically exhausted that he could not deliver. Gave chloroform, and passed my hand; brought down both feet and delivered body, but was compelled to turn child's body up over the mother's abdomen and extract the head with forceps, but was not able to effect this in time to save the life of the child, a male, weight thirteen pounds; very slight laceration of the perineum; mother had phlebitis, involving one limb from the toe-nails to the abdomen, the worst case I have ever seen; she, however, eventually made a good recovery.

October 2, 1877. Mrs. M., primipara; vertex; but an exceedingly short, sharp labor, with a stellate laceration of the cervix that I assisted her medical attendant to run up a few months afterward; child, boy.

October 25. Mrs. N.; vertex; normal; boy.

November 8, 1877. Mrs. J., primipara; vertex; tedious; girl; profuse flooding, checked by passing a lump of ice into the uterus; gave ergot; recovery normal.

December 11, 1877. Mrs. G.; vertex; female; normal.

December 27, 1877. Mrs. H.; vertex; female; normal.

February 19, 1878. Mrs. C.; vertex; female; seven months; lived three days; mother had pains during three days; tried to allay them with anodynes; failed; normal recovery.

April 5, 1878. Mrs. W.; vertex; duration four hours; recovery normal.

April 11, 1878. Mrs. C.; vertex; duration three hours; female; normal.

June 4, 1878. Mrs. P.; vertex; four hours; male; normal.

June 9, 1878. Mrs. T.; breech; six hours; female; alive; normal.

June 13, 1878. Mrs. M.; vertex; one hour; female; normal.

June 25, 1878. Mrs. W., primipara; six hours; male; normal.

June 27. Mrs. B., primipara; vertex; tedious second stage, head would not descend into pelvis; forceps; took two hours to deliver after forceps were locked; perineum badly torn; washed and sewed up at once; healed nicely; made a normal recovery.

July 20, 1878. Mrs. T.; vertex; duration 36 hours; thin, hard cervix; gave morphia, and suspended labor for ten hours, when pains returned in fine style, with condition of cervix entirely changed for the better; female; recovery normal, except that during four days the urine had to be drawn with the catheter, *which the patient did for herself after the first time.*

July 31, 1878. Mrs. H.; vertex R.; female; four hours; normal.

August 6, 1878. Mrs. R.; vertex L.; male; six hours; normal.

August 10. Mrs. B., primipara; vertex R.; six hours; female; normal.

August 14. Mrs. N.; breech; six hours; male; large; normal.

August 23. Mrs. L.; vertex R.; six hours; owing to the extreme nervousness of this patient, gave chloroform very freely; normal recovery.

September 8, 1878. Mrs. W.; vertex R.; six hours; male; normal.

September 8, 1878. Mrs. B.; vertex L.; tedious in second stage, forceps; got up a little more slowly than might be termed normal, but a good one finally.

November 10, 1878. Mrs. W., primipara; vertex R.; eighteen hours; male; normal.

November 15, 1878. Mrs. W., primipara. eighteen hours; female; normal.

December 3, 1878. Mrs. M,; face; anterior; nineteen hours; male, ten pounds; recovery normal.

December 30, 1878. Mrs. F.; vertex; three hours; female; normal, notwithstanding Mrs. F. had a very decided mitral regurgitation.

January 20, 1879. Mrs. W.; vertex R.; duration thirty-six hours; I was not called until thirty hours had passed; abdomen so ponderous that I am certain the uterus lay far outside of the pubic arch, with its fundus directed forward and the cervix directly toward the promontory of the sacrum. Fortunately the ostium vaginæ was so voluminous that I easily passed my rather small hand, else I could not possibly have made out the presentation. Liq. amnii excessive, the woman having most agonizing pains, but apparently making no progress. She was also excessively obese. I should have sent for counsel, only I was ten miles in the country, the night bitterly cold (30°—), the wind blowing a hurricane, the family too poor to pay for counsel, no one but the husband in reach whom I could send, and no one in the town at that moment for whose judgment I cared a straw. Ruptured the membranes; procured a long and large farmer's roller towel, pinned it firmly around the abdomen, and made the patient lie strictly on her back. I placed my hands under the uterus, and lifted during each pain, and finally had the satisfaction of having the head engage in the superior strait, after which the child, a moderate-sized female, came like a bolt from a catapult. The mother made as good a recovery as could be wished.

January 18, 1879. Mrs. B., primipara. Vertex; R.; thirty hours; male; large; recovery good.

April 2, 1879. Mrs. H., IIpara. Vertex; R.; four hours; female; had slight metritis; eventually good recovery.

April 19, 1879. Mrs. C., a feeble consumptive. Her child born before I arrived; placenta lying in vagina; flooding furiously; quickly removed placenta; checked hemorrhage by injecting water at temperature of 120°. Mrs. C. made a slow, but fairly good recovery.

April 29, 1879. Mrs. H. Vertex; R.; three hours, female; normal.

May 2, 1879. Mrs. R., primipara. Vertex; R.; seven hours; Female; recovery normal.

May 11, 1879. Mrs. W. Vertex; left; female; ten hours; normal.

June 8, 1879. Mrs. H. Vertex; R.; male; time not noted; normal.

June 19. 1879. Mrs. C., primipara. Vertex; R.; thirteen hours; male; large; normal.

August 6, 1879. Mrs. D. Vertex; R.; female; twelve hours; normal.

August 15, 1879. Mrs. R., primipara. Vertex; L.; thirteen hours; seemed an easy labor; child, a small, poorly-nourished male; placenta normally delivered. Nevertheless, I was apprehensive of trouble, because of the quite decided swelling of her limbs, dating from one month prior to confinement, with scanty and decidedly albuminous urine which I had failed to notably increase by, as I thought, appropriate medication. I was called away from the house to see another patient only two blocks away, and went soon after the completion of her labor. I had not been gone ten minutes when a messenger came to call me back, saying Mrs. R. was in a "fit." Hastened back and found her in a most violent convulsion, face purple with congestion, the bloody froth being hissed though her clenched teeth, and the whole body jerking with the spasms. Tied up an arm and quickly opened a vein and bled her at least sixteen ounces, when the spasms ceased. Tightened her bandage, examined to see if the uterus was well contracted, gave ten grains of calomel as soon as she could swallow, and a hypodermic of morphia, and at the end of two hours went home. Labor was completed at three o'clock in the morning. At 9 a. m. of the 18th, was called to go eight miles in the country to another obstetric case, so called on Dr. Hawes and asked him to watch Mrs. R. until I returned. At 5 p. m., 16th, he found her again in convulsions; bled again, and gave morphia hy-

podermically. The convulsions ceased under the influence of the venesection, and did not again recur. Nine days' attendance sufficed to see her fairly recovered, and in twenty days the albumen had entirely disappeared from her urine. Eighteen months afterward she was again confined, under the care of some physician in the State of Kansas, whither the family had gone—child, a large, well-nourished female, and no trouble whatever. In the spring of 1883 they moved back to Colorado. May 27, she again consulted me. Pregnant for the third time; limbs enormously swollen; œdematous urine scanty and half albumen; constant and agonizing headache, and most uncontrollable vomiting; could seemingly retain no food or medicine in the stomach whatever. June 3, I called counsel. By this time she was having slight convulsions occasionally; thought to be in about the fourth month; marked heart murmurs. My notes do not state more. We decided to sacrifice the ovum in the hope of saving the mother's life. I pushed a rubber No. 10 catheter four or five inches into the uterus between the membranes and uterine walls, and left it there on the night of the 4th. Labor pains came on, and in two hours she was delivered of a four-months' fœtus, secundines coming away without difficulty, and only a very moderate flowing. June 26 was the last visit. Albumen, only a trace; swelling and œdema gone from the limbs; appetite good; no nausea; strength being rapidly regained. The family soon moved back to Kansas, and I learn she has had two children since, and is at the present time in the enjoyment of fair health.

August 16, 1879. Mrs. M., primipara. Vertex; female; lingering; second stage; forceps; recovery normal.

September 1, 1879. Mrs. M. Vertex; short labor, under rather profound chloroform anæsthesia; child, a large male. This woman I had assisted in the operation of sewing up a stellate cervical rent a little less than two years before. Now used the chloroform quite freely, hoping to prevent a recurrence of the former accident. Whether the anæsthesia had the desired effect or not I cannot certainly tell; I do know the cervix was not torn. Recovered soon and perfectly.

September 6, 1879. Mrs. W. Vertex; male; normal.

September 28, 1879. Mrs. W., IIpara. Vertex; male; large; forceps because of prolonged second stage; excellent and quick getting-up. This lady had the breech presentation September 24, 1879, followed by phlebitis, etc., narrated in the preceding pages.

October 2, 1879. Mrs. DeV.; vertex; short labor; female; getting up somewhat retarded by mastitis; lanced breast; final recovery good; has borne children since under my care without a recurrence of the mastitis.

October 4, 1879. Mrs. J.; vertex; female; normal.

October 9, 1879. Mrs. B.; vertex; female; normal.

October 10, 1879. Mrs. P.; vertex; normal.

November 16, 1879. Mrs. N.; vertex; normal.

November 23, 1879. Mrs. S.; vertex; normal; child female; born alive, but lived only one hour.

January 6, 1880. Mrs. C.; vertex; male; normal.

January 15, 1880. Mrs. S., primipara; consumptive; with a large cavity in left lung; much emaciated; family so poor as to almost lack the absolute necessaries of life; vertex; male; large and plump; labor easy and short; good recovery in the usual time; did not nurse her child. General health improved for over two years, when I waited on her again, after which she rapidly declined, and died from her lung troubles.

January 23, 1880. Mrs. P.; vertex; lingering second stage; forceps; female; normal recovery.

January 24, 1880. Mrs. W., primipara; vertex; male; very large; required the use of catheter for four days; had mastitis; lanced one breast; recovery ultimately good.

January 31, 1880. Mrs. P.; vertex; labor short and easy; female; small; normal.

February 19, 1880. Mrs. C., a very small woman, a bad hunchback, and a hæmophile; primipara; had flooded profusely at her former labor; vertex; labor slow; child male; weight ten pounds. Gave a teaspoonful fl. ex. ergot when the head reached the perineum, and filled hypodermic syringe for use if the emergency should come. After placenta came, flooded so frightfully that I gave the hypodermic of ergot in the thigh; injected hot water into the uterus quickly controlled the bleeding, but finally had a little abscess at the site of the hypodermic of ergot. She made a good and quick recovery; nursed her child.

February 21, 1880. Mrs. R., primipara; vertex; at the seventh month; child lived only a few days; patient made good recovery. She brought on the premature labor, as I am fully persuaded, by the persistent use of hot water, used by the vaginal douche instrument, and Davidson syringe. Some

lady friend told her that owing to her age, about 30, she would have a very "hard time," and to prevent it she must use the hot water. She had been putting in most of her spare time for about a week in that work. When I was called the mouth of the uterus was two inches wide and the waters drained off, but the pains very moderate. I am satisfied that she did not intend to bring on premature labor. I have often made use of the hint obtained by this case, and used hot water with excellent effect where dilatation was slow and unduly painful, with a thin and rigid os.

March 6, 1880. Mrs. L., primipara. Vertex; labor short and easy; male; normal.

April 6, 1880. Mrs. T., IIpara. Vertex; R.; male; normal.

May 2, 1880. Mrs. S., VIpara. Vertex; R.; two hours; male; normal.

April 29, 1880. Mrs. F., primipara. Vertex; female; mastitis; breast lanced; raised child on bottle; recovery eventually good.

May 3, 1880. Mrs. K. Vertex; female; normal.

June 21, 1880. Mrs. S., primipara, aged forty. Vertex; delay in second stage: forceps; placenta so firmly attached directly to fundus uteri that it had to be peeled off by my finger-nails; gave ether; perineum torn; washed and carefully stitched at once; united well; good recovery in two weeks.

July 13, 1880. Mrs. T. Vertex; male; normal.

August 9, 1880, Mrs. J. Vertex; female; normal.

September 12, 1880. Mrs. B. Vertex; easy labor; male; normal. The meatus urinaries in this child opened at the frænum preputialis beneath the glans penis; child died when two weeks old.

September 14, 1880. Mrs. W., primipara. Vertex; male; normal.

September 16, 1880. Mrs. T., primipara. Vertex; female; normal.

September 17, 1880. Mrs. M., primipara. Vertex; male; very large; labor tedious; very nervous woman; hardly sane; metritis and septicæmia; dismissed after an attendance of twenty days; eventually made good recovery.

September 25, 1880. Mrs. D., primipara. Vertex; male; normal.

September 30, 1880. Mrs. A., primipara. Vertex; female; normal.

October 6, 1880. Mrs. J., primipara. Vertex; male; normal.

October 19, 1880. Mrs. R., IIIpara. Vertex; female; normal.

October 21, 1880. Mrs. M. Vertex; male; normal.

October 21, 1880. Mrs. S. Vertex; male;

October 25, 1880. Mrs. N. Vertex; female; normal.

October 25, 1880. Mrs. J., primipara. Vertex; female; normal.

October 28, 1880. Mrs. W., primipara. Vertex; female; normal.

October 29, 1880. Mrs. W——c, IIIpara. Vertex; male; normal.

November 10, 1880. Mrs. K., primipara. Vertex; female; normal.

(*To be continued.*)

REPORT OF A CASE OF SICK-HEADACHE.

BY J. C. CUMMINGS, M. D.,

Of Beaver Creek, Minnesota.

Many are the victims of this much dreaded disease (or symptom), which, like many other diseases that the human race are subject to, are alike amenable to treatment by medication, although many of the almost innumerable remedies which are at the physician's command in this enlightened age of medical science, have and do fail to produce the desired effect, which effect we can attribute to many causes, as climate, constitution, and the preparation of the drug used. It should not only be the aim of the physician to procure the most reliable preparations of medicines, but to make climate and the constitutions of each and every patient a study of as much value as that of medicine, which I consider of as much importance or essential to success, and very much more than many of the fictitious problems on which the agitators of medical science are and have been filling the minds of the medical profession, which for the most part must inevitably fall, like many preparations of medicine, into disuse, and become one of the things of the past. Considering then the constitution, climate, condition, and carefully studying the case before you, your diagnosis made, you are ready to prescribe; and last, but not least, consider carefully the financial condition of your patient before you, as this is one of the most essential considerations, as no man is more worthy of a compensation for his services than a physician. Better had he do nothing, than to exhaust his energies and vital powers for naught. You will pardon me from deviating from the subject matter. Case as follows:

Mr. O. A. H. came under my care in April, 1885, age 36, weight 170 pounds,

suffering from periodical attacks of sick-headache occurring about once in two weeks. He had been the subject of this loathsome affection for a period of twelve years, and the degree of severity was in proportion to the number of years affected. The subject was particularly temperate in all his habits, was a lumber dealer, led an active out-door life. Being compelled to abandon his business pursuits for five days each month, he anxiously sought relief, which he had previously sought in vain, and had almost given up in despair, and considered himself a subject doomed to suffer without relief. The attacks came on in the morning, and continued for a period of twenty-four hours with increased severity, until becoming so fatigued that he would pass into a profound sleep, which would last from two to six hours, awaking experiencing none of the symptoms of headache but a feeling of profound depression and lassitude, which continued correspondingly to that of incubation. After a thorough examination, I found him to be a subject of chronic liver trouble, in whom the usual train of symptoms peculiar to these cases were found which are so familiar to the practitioner. I shall not enumerate them. Prescribed nitro-muriatic acid in ʒj doses t. d. in ℥vj of aqua after eating, and the following to be taken as soon as the first symptoms of the headache appeared:

℞.	Morphiæ acetat.,	gr. iiiss.
	Caffeine citrate,	gr. iij.
	Ammoniæ muriat. "s.,"	ʒj.
	Spirits ammoniæ aromaticus,	ʒjss.
	Comp. elixir sumbul,	ʒijss.
	Aqua menth. pip., ad. q. s.	℥iv.

M. Sig.—ʒij every ten or fifteen minutes until five doses were taken, if the symptoms continue unabated.

At the usual period the symptoms came on, and the above was administered at once, and I am happy to say the symptoms disappeared with the third dose, never again to appear.

The patient has been under my observation up to the present time. Using his own language: "I consider myself cured, and consider it (the medicine) of more value than the best farm in the northwest." As he begins to show signs of biliousness, I prescribe the mineral acids in doses above given.

I prescribed the same to one other patient, who had been a sufferer from the same disease (headache), but not of a bilious temperament, the fourth dose being sufficient to abort the attack, which has as yet failed to return (16 months ago), under constitutional treatment peculiar to the requirements of the case.

I take pleasure in recommending this formula to the profession for trial, as it has in these cases proved to be an efficient remedy with me.

(*Continued from page* 432.)

Case 3. Sarcoma Substituting the Sixth Cervical Vertebra.

The last specimen I show you is an interesting one, taken from Mr. D., æt. 62 years, a native of South Carolina, who was sent to me from Norfolk, in the latter part of September last. In December, 1885, nine months prior to his coming, he fell from a raised platform, striking the back of his head and neck against a railing which surrounded the dais from which he fell. He was senseless a few moments, but recovered so as to walk to a carriage near by, and he was taken home, where any attempt at reclining caused for several days intense pain in the occipital region and nausea. Two weeks after he was able to move about with a cane, and early in March returned to his work of a machinist with a stiff neck and a tendency to nausea if he attempted to turn it.

In June there appeared on the left side of the neck what he called a kernel, very sensitive to pressure, and was accompanied by intense neuralgic pain in arms, and jerking of the brachial muscles, and as these symptoms increased a restlessness that could only be appeased by bringing him to Baltimore, as he felt confident of recovery if he could only reach there.

When I first saw him he was rather well nourished, was in excellent spirits and presented no abnormal aspect, except that his head projected forward and there was a slight rigidity of the scaleni on the left side simulating a spastic condition of these muscles, very sensitive to pressure. He was unable to move his head toward the left or bend it back. There was no disparity in his pupils or paralysis about his tongue. His grip was diminished more markedly on the left side, and great increase of patella reflex on the same. He was utterly unable to stand alone with his eyes closed, and had the uncertain gait of an ataxic. Soon he began to complain of a constriction about the abdomen and tingling in his feet and legs—the paralysis being much more marked at first in the

upper extremity, and later absolute in lower extremity, bladder, and last of all in the rectum. The Faradic current showed a degenerative reaction in the muscles of the arms and legs, though much subjective relief was given by its employment. At no time was there priapism so common in lesions about the cervical cord. For one day there was inability to speak and trouble in deglutition, but this passed off.

At first I was inclined to suspect a myelitis due to injury, but as the prominence gradually increased in the cervical region I made the diagnosis of a foreign growth most likely sarcomatous. The treatment consisted in absolutely no medication except an occasional laxative (he could not take opium for his pain), and the drawing of his water, in which I am indebted to Dr. Clewell for his kindness in seeing him, alternately, as well as to Drs. Platt and H. Thomas for suggestions. I append the post-mortem examination of Dr. Councilman, who kindly made a most thorough one, and, I am glad to say, found my diagnosis correct. Unfortunately, the case was published throughout the country as a man living with his neck broken for eight months. As far as this can be corrected by this statement, I hope it will be so.

NOTES ON AUTOPSY.

Made by Dr. Johnson, November 1, 1886.

Body of medium size, strongly built, emaciated, slight icterus.

The thorax, arms, and entire posterior portion of the body emphysematous.

Post-mortem discoloration along surface veins.

Neck extensively emphysematous, more on left side.

On left side of neck, along the vertebral column, a hard swelling, apparently the size of a walnut, could be felt.

One of the cervical vertebræ, apparently fifth, very movable. The head rolled freely from side to side, in whatever position it was placed. Incision made along vertebral column from occiput to sacrum. In cervical region there was a space with dura mater of cord at bottom about an inch wide, occupying place of sixth cervical vertebra.

Cord examined from lumbar to cervical region showed no change.

Cervical vertebræ were removed and sawn through.

The entire sixth vertebra, with the exception of articular facets and some small pieces of the arch and spine, was missing. The intervertebral substance above and below thick and rough. The body of the seventh cervical vertebra was eroded, spongy, and reduced to half-normal size. The body of fifth also eroded, but not so much. There were also eroded surfaces on the arches and spines of fifth and seventh vertebræ, on left side.

On the left side, lying along the seventh vertebra, filling up the loss of substance in its body, and extending up alongside to the fifth vertebra, was an irregular, firm tumor mass, about the size of a small walnut.

Microscopic examination of this showed it to be a round-cell sarcoma of the large-celled variety.

Brain slightly hyperæmic, and meninges œdematous. Dura adherent along longitudinal sinus.

Heart soft and flabby.

Lungs œdematous.

Abdominal organs showed no change of any note.

The cord was soft and much altered from post-mortem changes. Absence of myelitis was shown by teasing fresh particles. No compound granular bodies were found.

W. T. Councilman.

DISCUSSION.

Dr. F. T. Miles said the paralysis in the arms in Dr. Johnson's case recalled a case in his practice which resulted from pachymengitis and compression in the cervical region. Paralysis in the upper extremities results from compression in this region.

Dr. L. McLane Tiffany then related a case of a woman æt. 32 years, married, and has a family. Four years ago, while carrying a child, the pain appeared, and increased until after the delivery of the child, which was six months. After another year, and before a second confinement, the pain in the knee again appeared, and after the birth of this child it disappeared. The knee then began to swell. Nine months ago she lost the power of extension, and the knee gradually became more and more fixed, until it finally became fixed at an angle of about 60°. She can bear no weight upon this extremity, and in consequence is obliged to use crutches.

Diagnosis of malignant growths within the condyles was made. There was no fluid within the joint. The *patella* lay flat upon the condyles, and, notwithstanding the leg was rigidly flexed at an angle of 60°, it was freely movable *laterally*. Malignancy is the only trouble with which he is acquainted that can so relax the tissues around the joint as to permit of lateral movement of the patella when the limb occupies such a posi-

tion as in this case. It was upon this point that the diagnosis was made.

There was no history of injury. The leg was amputated.

Dr. Chambers thinks this case illustrates Hilton's theory of neurotic origin of the flexed knee without fluid in the joint. He don't think lateral movement of the patella in a flexed knee sufficient to justify a diagnosis of malignancy.

Dr. N. G. Keirle showed the skull from a case of gunshot wound. The bullet had penetrated the eye, passed through the ethmoid bone, and striking against the inner table of the vault of the skull near the junction of the saggital and lambdoid sutures, glanced off, and was found imbedded in the occipital lobe of the brain, two inches from its point of contact with the skull.

He showed a second skull that had been fractured in the line of the saggital suture. The force of the blow had caused the bones to be crushed in upon the longitudinal sinuses.

He has made a number of experiments upon the skull in dead subjects, and from his results is unable to sustain the theory of "increase of resistance acquired by dead tissues."

Dr. L. McLane Tiffany thinks Dr. Keirle's first case disproves the directions laid down by Flurhrer, of New York, who, from a single successful case, advocates trephining of the skull for the removal of bullets in the brain. He don't think success would have followed such a procedure in this case.

Dr. Keirle also exhibited an elbow with a lateral dislocation outward of radius and ulna. The epitrochlear had disappeared, and there was a fracture of the olecranon which had been repaired by firm fibrous union. At the coronoid fossa there was an osteophytic growth supposed to be the epitrochlear, which having become fractured, had attached itself to this position.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Regular meeting, February 28, 1887. Laurence Johnson, M. D., President, in the chair.

Dr. P. Albert Morrow read a paper entitled

The Duration of Syphilogenic Influence in Relation to Marriage.

The following conclusions were drawn:

1. The facts of every-day observation show that there is nothing constant in contagion, nothing certain in heredity. Many men marry with a syphilis in full activity of secondary manifestation, and never infect their wives or transmit the disease to their offspring. These negative observations are, however, entirely valueless as a basis for estimating positive results.

2. The modern division of syphilis into secondary and tertiary periods, based upon anatomical forms and processes, does not furnish a safe criterion for determining the contagious or non-contagious character of the lesions.

3. The chronological completion of the secondary stage does not always mark the definite disappearance of the virulent principle; clinical experience shows that late lesions are exceptionally, but none the less certainly, the source of contagion.

4. While in the immense majority of cases the contagious activity of syphilis and its susceptibility of hereditary transmission cease after the third or fourth year, yet well-authenticated observations prove in the most positive manner that these qualities sometimes continue in force much longer, and may be manifest in the fifth and sixth year of the disease, and even later.

5. The aptitude of syphilitic parents to procreate diseased children may persist after the cessation of all specific manifestations; the contagious stage of syphilis is not, therefore, the exact measure of the duration of hereditary influence.

6. The precise date in the evolution of the diathesis when the syphilitic organism undergoes that radical transformation which marks the limit of its contagious or transmissive power, does not admit of mathematical expression.

7. It is probable that this limit varies in different cases, and that many circumstances contribute to advance or defer it.

8. The type of the syphilis, the constitutional peculiarities of the patient, the character of the treatment, the presence or absence of certain conditions which are recognized as factors of gravity in syphilis, all exert a modifying influence.

9. All these elements should be taken into consideration in deciding upon the admissibility of a syphilitic man to marriage; each case should be studied upon its individual merits.

10. The direct paternal transmission of syphilis, without preliminary infection of the mother, may be classed among the most conclusively established facts of medical science.

11. It is, therefore, a dangerous doctrine to teach that the sole risks a syphilitic man

introduces into marriage consist in the contagious accidents he may bear upon his person.

12. The arbitrary designation of a limit of three, or at most four years, as perfectly safe for a syphilitic man to marry, with or without treatment, and irrespective of the actual existence of specific lesions, is unwarranted by science or the teachings of experience.

The conditions of admissibility to marriage formulated by Fournier are much broader, more scientific, more safe. These demand a mild or medium type of the disease, an advanced age of the diathesis, three or four years as the minimum, and a prolonged immunity, eighteen months at least, from specific accidents; if these guarantees of safety are further fortified by sufficient specific treatment, a reluctant consent is given, marriage is tolerated rather than advised.

Dr. F. N. Otis, to whose paper Dr. Morrow had referred, replied at length, and said that he was not alone in claiming that there was a limit to the duration of the syphilitic contagion or its hereditary power; nearly or quite all writers admitted it; it was only a question of time. The majority indeed admitted that few cases of contagion or hereditary transmission took place after the fourth year, or even the third year. That was all he claimed. He did not think the inference could be drawn from his paper that he advocated marriage in all cases after the third year, although he had not known any evil results after that length of time had expired. Reported cases of transmission or inoculation of syphilis after the fifth year were very few, and were unreliable, because other sources of contagion had not been excluded. He claimed that the late lesions of syphilis, or so-called third stage, were sequelæ of syphilis, as nephritis might be a sequela of scarlet fever after the disease had ceased to be contagious.

After further discussion, F. R. Sturgis read a paper on

The Supposed Virus of Chancroid.

In answer to the question which he had propounded, "What is the virus of chancroid?" he answered, "There is none?" "Is it not the result of acute inflammation?" "I believe it is." "What are the sources of chancroid pus?" "They were secretions from different sores or inflammatory processes, provided they were applied to an irritated abraded surface." These were also capable of auto-inoculation, as in ordinary chancroid.

Dr. R. W. Taylor said these views were held almost alone by Dr. Bumstead in 1876. He was glad to see Dr. Sturgis change his ground.

Dr. Sturgis claimed this paper was only additional to another formerly published by him.

GYNÆCOLOGICAL AND OBSTETRICAL SOCIETY OF BALTIMORE.

Regular meeting, held February 8, 1887. First Vice-President, P. C. Williams, M. D., in the chair. Wm. E. Moseley, M. D., Secretary.

Dr. L. E. Neale exhibited a very interesting case of

Fœtal Monstrosity,

alive, and nearly one month old, which he thought was probably caused by maternal impressions received during the second month of pregnancy. The case occurred in the outdoor obstetric department of the University of Maryland, over which Dr. Neale has charge.

History.—Sarah Jefferson, mulatto, aged twenty-six years, married, Vpara. A well-developed, evenly-proportioned, rather fair-looking, perfectly healthy, and normal woman. She was married at the age of seventeen years, has always been healthy, has borne perfectly healthy children, and no physical abnormality can be found in her husband.

Her last menstruation was in June (latter part?), 1886. During the following August she visited Druid Hill Park and was very much interested with the sea lions, then on exhibition in their aquatic home in that public resort. Nothing unusual occurred during her gestation, which terminated in labor, January 16, 1887.

She was attended by Mr. W. P. Malone, medical student at the University of Maryland, through whose kindness I am supplied with the case and history, for which I am happy to make public acknowledgment. The labor was normal (L. O. A.), save that the placenta was retained and required the internal introduction of the hand for its removal. Puerperium normal. A rather small, puny male child was born alive, its size being about that of an ordinary eight months' fœtus, with the following peculiarities of development. All parts of the body are perfectly natural, except the two upper extremities.

The left arm is represented by a normal humerus and surrounding soft parts. The

forearm is aborted in its development, the radius and ulna being indistinct, the elbow joint anchylosed, and the hand terminating in two fingers webbed together, with nails complete, and thumb freely movable.

The arm is bent backwards, hand somewhat flexed and pronated (rotation at imperfectly formed wrist joint) with thumb downward, somewhat like the flap of a seal.

On the right side, both arm and forearm are wanting. An aborted hand, composed of an irregular finger with no nail and thumb with nail, springs directly from the shoulder joint, which is movable. This extremity, in appearance and motion, closely resembles the fore-flap of a seal. The child is otherwise natural and is thriving fairly well.

I shall not trespass upon the time of the Society by entering into a study of this subject, but will content myself at present by merely quoting a few explanatory remarks from the very recently published second volume of Tarnier's "Praité de l' Art des Accouchements," 1886, p. 419–20.

The Unitarian monsters of Autosites constitute the first order in the classification of Geoffroy Saint-Hilaire. This order comprises:

1. Deviations existing in the extremities.
2. Deviations existing in the trunk.
3. Deviations existing in the cranium.
4. Deviations existing in the face.

Each genus comprises several families, and each family several species.

1. *Ectromeles.*—According to Dareste, it appears that the cause of arrest of development of the limbs should be sought for in certain viscious disposition of the amnion, which in pressing upon the limbs impairs their development (?). According to the variety of the defect of development, ectromeli are subdivided into three classes of monsters.

A. *Pholocomeles.*—Here the want of development is confined to the two segments of the extremity, the terminals, viz., hands or feet having acquired their normal dimensions. Centrifugal defect.

B. *Hemimeles.*—Here it appears as if the arrest of development proceeded inversely to the above (A.), viz., from the periphery towards the trunk or as centripetal defect. The hands or feet, as well as forearms and legs, remain rudimentary, while the thighs and arms attain normal dimensions.

C. *Ectromeles.*—Where the arrest of development affects all the segments of the limb which is represented by a small stump in which may be recognized with difficulty the several segments.

Strictly speaking, I do not think that my case comes under any one or two of these types, hence I will leave its classification and nomenclature an open question.

Dr. P. C. Williams reported a case of

Placenta Prævia.

Late in the afternoon of June 16, 1886, Dr. M. called at my house and requested me to go with him to see his wife, who was about to be confined with her first child.

I went at once, and found Dr. E. R. Walker awaiting our arrival.

From these gentlemen I ascertained that Mrs. M. was 36 years of age, had been married about two years, and although not robust she had enjoyed reasonably good health. At times she suffered from neuralgia and other slight malarious symptoms incident to her residence upon the Eastern Shore of Maryland. With this exception her health continued good until the sixth month of her pregnancy, when she had occasional attacks of very severe headache accompanied by dimness of vision. Her urine was normal.

About the close of the seventh month she had a uterine hemorrhage. Examination revealed a long, narrow, rigid vagina, that rendered it difficult to reach the os uteri. The os was undilated, and the cervix still projecting into the vagina. Finding no signs of beginning labor, and no history of injury, and no reasonable explanation of the hemorrhage, the doctors were naturally led to suspect the existence of placenta prævia.

From this time Mrs. M. was confined to the house, and spent the greater part of her time either on the lounge or in bed, and was under the constant supervision of her husband or Dr. Walker.

About two weeks later another hemorrhage supervened, but not sufficiently severe to excite serious apprehension, or seriously to impair Mrs. M.'s strength. A week later moderate bleeding again commenced, but still there were no indications of commencing labor.

Vaginal examination showed that the os was still closed, but the cervix had disappeared. A few days later slight uterine pains were experienced, and there was continuous, moderate oozing of blood, which was increased by any movement made by Mrs. M.

At this period I was called in. I found the vagina unusually long, narrow and rigid, the os uteri had dilated so slightly that I had some difficulty in passing my finger into the cervix.

I thought, after careful examination, that

I could feel the placenta covering the os, and was fully satisfied that we had to deal with a placenta prævia. The parts were all so rigid and unyielding, and the os so slightly dilated, that I felt that active interference was improper. I accordingly advised the tampon, thinking that it would not only restrain the bleeding, but would soften the uterus and vagina, and render it possible to do something towards the delivery of the child.

About three o'clock the following morning (January 17) I was sent for. I found that decided labor pains had set in. I removed the tampon, and found that it had done good service. There had been no hemorrhage, the vagina was still firm, but not so unyielding as before, the os uteri had softened and was dilatable. I could now clearly define an almost central placenta prævia firmly attached to the left side of the os—on the right side of the os I found that the placenta could easily be separated, and that with some difficulty I could pass the edge of the placenta and reach the uterine cavity.

The time for speedy termination of the labor had come. How should it be done? With the forceps? Or by version? The vagina being so long, narrow, and rigid, as I have described, I felt that version would be extremely difficult if not impossible. Therefore, I rejected that method, and determined to try the forceps. By careful manipulation I succeeded in adjusting the forceps in utero without the loss of much time, and without producing much hemorrhage. I immediately made strong traction and brought the head fairly down against the placenta, and to my great relief found that it effectually stopped the bleeding. From this point to the extraction of the child there was no loss of blood. Not a teaspoonful was lost during the remainder of the labor. Chloroform was administered, and its moderate influence maintained until the completion of the labor, which was rendered very tedious by the extreme narrowness of the vagina. After exhausting and strenuous effort extending through two to two and a half hours, I succeeded in delivering a large, well-developed, but dead child.

Before the extraction of the child, in order to guard against uterine relaxation or post-partum hemorrhage, I administered a large hypodermic dose of ergot, which produced and maintained firm contraction of the uterus. There was no difficulty in the delivery of the placenta. In a short time Mrs. M. aroused fully from the chloroform, her color returned, her circulation seemed good, and she conversed clearly and intelligently. After giving her a cup of hot coffee and talking awhile with her, I left her, congratulating myself on the safe termination of so critical a case.

After breakfast I went to enquire about my patient, and to my great surprise and sorrow I found that she had died suddenly about an hour before my arrival.

Upon inquiry I ascertained that everything progressed favorably for about two hours after I left her, when she was suddenly attacked with intense dyspnœa and restlessness, and died in an hour thereafter!

What was the cause of her death?

There was no post-partum hemorrhage She was permitted to raise herself upon her pillow, and to turn upon her side.

Could this slight effort have produced syncope? and could that syncope have caused a clot to form in her heart? Or is it possible for a heart clot to form without a preceding syncope?

DISCUSSION.

Dr. H. M. Wilson thought that probably both the hemorrhage and the chloroform contributed toward the fatal result in the case reported. He had lost one case from placenta prævia and considered that his patient died from blood clot. Dr. Wilson had never experienced any trouble from the use of chloroform during labor but did not feel perfectly satisfied as to how thoroughly we are justified in using it instead of ether, which is so generally considered safer.

Dr. W. E. Moseley considered that, so far as regarded the cause of death, the history of the case as reported pointed very directly to concealed hemorrhage.

Dr. B. B. Browne thought the intense dyspnœa, pain, and uneasiness about the chest were nearer the symptoms of heart-clot than of concealed hemorrhage.

Dr. L. E. Neale thought it of far greater practical importance to consider the treatment of placenta prævia rather than to speculate upon the cause of death in the individual case reported. Placenta prævia is recorded as having a maternal mortality of 24 to 40 per cent., while two-thirds of the children are lost before full term, and one-half of those born viable die during the first ten days.

This fearful death rate clearly indicates (1) the necessity of a diagnosis *as early as possible*, in order to (2) apply the proper treatment. And inasmuch as the woman is never safe until the womb is thoroughly empty, we should disregard the life of the

child to save the mother, and hence he questioned the advisability of allowing such cases to go to full term.

Of course there were special conditions attending special cases that must be met by special modes of treatment, but of all methods thus far proposed, unquestionably delivery by Braxton Hicks' bimanual version, *wherever practicable* (and there are many cases where it is impracticable), had given the best results.

In the *American Journal of Obstetrics*, December, 1884, Lomer reports the following statistics of (cases of placenta prævia treated by bimanual version):

	No of Cases.	Deaths.
Hofmeier	37	1
Behm	40	0
Lomer	101	7
	178	8

Giving a maternal mortality of 45 per cent.! The following table, "*which places the statistics in the most unfavorable light possible, includes every single case, even such as had been treated according to other methods, previous to the employment of the bimanual method of turning:*"

	No. of Cases.	Deaths.
Hofmeier	47	4
Behm	53	4
Lomer	136	13
Total	236	21

Mortality about 10 per cent. Dr. N. did not consider it the proper time or place to describe the details of this very simple and easy operation, but inasmuch as it required a dilatation of the cervix uteri only sufficient to admit one, preferably two fingers, it offered the advantage of being applicable early in the treatment of these cases.

Having once turned the child and seized a foot, our active manœuvres cease, and delivery may be effected spontaneously or by manual extraction according to the requirements of the case. "The practical results of the induction of premature labor plead still more effectively in its behalf. Thus Dr. Gaillard Thomas reports eleven cases with but two deaths, one resulting from post-partum hemorrhage coming on several hours after delivery, and one from puerperal fever. Hecker lost three cases in forty, Hoffmann two cases in thirty, and Spiegelberg four cases in seventy-four early deliveries. More recently Murphy has reported fifteen cases without a single death." (Lusk edition, 1885, p. 594–5.) The tampon is applicable only in those cases where we have a long, narrow, firm, undilated, and undilatable cervix, and then only as a temporary measure, to be watched carefully and allowed to remain at most but four hours.

Given a case of supposed placenta prævia:

1. A positive diagnosis should be made *as early as possible.*

2. If labor has not set in spontaneously, induce it artificially.

3. Deliver by bimanual version whenever practicable.

Dr. W. P. Chunn had seen two cases of placenta prævia, one of which was delivered by Dr. Neale. He thought in most cases the line of treatment spoken of by Dr. Neale was good; but there were exceptions. In long, narrow vaginas, such as Dr. Williams had to deal with, manipulation is very difficult, and the use of forceps might be preferable to turning. He considered the use of the tampon good, and, as suggested by a friend of his, that a large bathing sponge would make a good tampon in case of emergency. The manner of applying a tampon he thought important. If possible, the woman should be in Sims' position, and the peritoneum retracted by his instrument. One unaccustomed to these manipulations would be surprised to find how much material a vagina fully distended would hold.

Dr. Browne considered that it would not be justifiable to use the means for making an early positive diagnosis in such a case as reported by Dr. Williams, where the cervix was long and conical, and the os undilated. The only means for making a positive diagnosis, dilatation would be very certain to bring on premature labor. He did not think we were called upon to make a positive diagnosis when but a light hemorrhage had taken place, but only when repeated hemorrhages had occurred and the patient's life was threatened. In some cases repeated hemorrhages even may take place and still there be no placenta prævia, and the patient go on to full term.

(*To be continued.*)

One Reason for an Urgent Call into the Country.

A French practitioner received a call one afternoon, about five o'clock, from one of his country patients, a farmer who had been in town at market all day, who requested him to drive over at once to see a member of his family. The case not appearing to be urgent, the doctor replied he would go in the morning. "Oh, that will not do at all," said the farmer. "I ask you to go now because I want a lift home, and to hire a trap will cost more than your visit."

Editorial Department.

Periscope.

Catheterism of the Air Passages.

The *Lancet* says that the introduction of a catheter into the larger air passages, for the purpose of local medication or mechanical dilatation, or to obviate recourse to tracheotomy, has been much facilitated since the introduction of cocaine into laryngeal surgery. A paper recently read before the Medical Society of the Charité Hospital at Berlin by Dr. Landgraf, clinical assistant (*Berl. Klin. Woch.*, 1887, No. 5), illustrates the ease with which the procedure is effected. He described a case presenting symptoms of stenosis of the left bronchus; the symptoms, which had gradually increased in severity, dating over two years. When admitted into the hospital last July, the patient was liable to dyspnœal attacks; and physical examination led to the above diagnosis. The constriction was at first thought to be due to compression, a view which was borne out by the presence of a small area of dullness over the manubrium sterni and to its right. There was no evidence that this was due to a tumor arising in the bronchial glands. The long duration of symptoms negatived the existence of a malignant tumor, and the absence of bacilli in the sputum set aside the notion of tubercular disease. Aortic aneurism was more probable; but this diagnosis lacked confirmation, the only positive sign being the area of dullness. It was therefore thought to lie between syphilitic stricture (the patient had contracted syphilis twelve years previously) and aneurism; and, since the former gave a more hopeful prognosis, the patient was placed under anti-syphilitic treatment. But the dyspnœal attacks increased in frequency, and measurement of the chest showed a diminishing capacity of the lungs. Further, an examination made at the beginning of October revealed what was thought to be a membrane deep down in the trachea. This appearance supporting the endo-bronchial character of the stenosis, it was resolved to resort to catheterism. The larynx was anæsthetized by a 20 per cent. solution of cocaine, and a 10 per cent. solution was injected into the trachea. The catheter was easily passed to a distance of 28.5 centimetres from the teeth (found subsequently to correspond to the tracheal bifurcation) without meeting any constriction. The catheterism was repeated at intervals, and on several occasions to a depth of 35 centimetres, with a view to traverse the left bronchus. The measure produced so much relief that at the end of the month the patient was well enough to leave the hospital. Unfortunately the diagnosis of stricture, which had been apparently confirmed by the relief of the symptoms, proved incorrect; for in a few weeks he returned, having had a severe asphyxial seizure, and shortly after died. The cause of the stenosis proved to be—what is by far the most common cause of such a condition—an aneurism of the aorta, which compressed the left bronchus. The condition which was mistaken during life for a membrane was an anæmic part of the right wall of the trachea. Although during life some irregularities in the mobility of the vocal cords were observed—on one occassion the right cord moving less on respiration and phonation, and on another the left cord appearing immobile in middle line—yet the dyspnœal attacks could not be referred to involvment of the vagus. They must have been due to the compression of the bronchus, for they disappeared directly the narrowing produced by that compression was mechanically relieved. Dr. Landgraf fully recognized the danger of resorting to such mechanical dilatation in aneurismal cases, and he would hesitate to catheterize in any case in which aneurism could be suspected. Nor is it quite easy to account for the great relief temporarily afforded by the measure in this case. The valuable point learned from it is the ease with which the air passages can be catheterized with the aid of cocaine, thus affording means to relieve strictures, as well as to apply remedies locally to ulcerated surfaces on the respiratory tract.

Submaxillary Calculus.

Dr. Collis Barry thus writes in the *Lancet:*

The following case is worthy of record on account of the unusual size of the calculus and the gravity of the symptoms resulting from its presence.

R. W., aged sixty-six, consulted me early in September last concerning a swelling beneath the lower jaw on the right side, which caused him extreme difficulty in swallowing. Flashing pains came on at intervals, and extended radially from the swelling upwards into the face and head, inwards towards the tongue, and downwards as far as the right

shoulder and arm. These symptoms had existed for about eight months, becoming gradually more severe; latterly the patient had begun to lose flesh, and his friends became alarmed at his condition.

Upon examination I found a hard substance corresponding in position with the submaxillary gland placed just below the ramus of the inferior maxilla, rounded in form, and more easily distinguishable from the outer side than from the interior of the mouth, and about the size of a small walnut. By pressure from the outside, a few drops of purulent discharge appeared at the orifice of Wharton's duct. There was no hardness or concretion at the mouth of the duct, as usually met with in cases of salivary calculus, and there was no induration of the cervical glands. Taking into consideration the gravity of the symptoms and the increasing loss of strength, I suggested early removal, but requested a consultation. Dr. Ainsley, of Hartlepool, saw the case with me, and confirmed my suggestion. On October 12, chloroform being administered by Dr. Ainsley, I proceeded to cut down upon the submaxillary gland by a vertical incision about a quarter of an inch anterior to the facial artery as it crosses the inferior maxilla, extending downwards about two inches; a second cross incision was made to make room. There was considerable hemorrhage from the submaxillary and other small branches of the facial. The whole of the gland superficial to the mylo-hyoid was removed, and the calculus could then be distinctly felt at the commencement of the duct, and apparently imbedded in the gland. A few of the posterior fibres of the mylo-hyoid were divided, and the calculus seized with vulsellum forceps and removed. Upon examination after removal, the calculus proved to be phosphatic, and measured one inch by half an inch approximately (the exact measurement in length being uncertain, owing to the crumbling of a portion of the calculus beneath the vulsellum forceps). The wound was plugged with lint soaked in turpentine, eucalyptus ointment and iodoform being substituted on the following day. The subsequent history of the case was one of uninterrupted recovery, the wound granulating freely and becoming entirely healed in three weeks from the date of operotion, all the symptoms previously complained of having entirely disappeared.

Remarks.—The ordinary method of removal by incision of the mucous membrane was impracticable in this case owing to the depth of the calculus from the surface of the mucous membrane. Erichsen mentions, as the largest calculus removed, one of the size of a small damson-stone; but, so far as I can ascertain, no mention has been made of a calculus of this size occupying so deep a position.

Recent Experiments on the Injection of Bacteria into the Veins.

Prof. von Fodor, of Buda-Pesth, communicated in a recent number of the *Deutsche Medizinsche Wochensch.* the results of his investigations into this subject. He had shown in a previous communication that hundreds of millions of non-pathological bacteria injected into the blood completely disappeared from it in the course of a few hours. By further experiments he showed that this power of the blood to destroy bacteria was not diminished by a moderate degree of anæmia, but was lessened by dilution of the blood with water, so far that the bacteria were destroyed more slowly and with greater difficulty. Even pathogenic bacteria disappear rapidly out of the blood, for example, typhoid bacilli, which even a few hours after injection are no longer demonstrable in the blood, whilst the animals are in some cases simultaneously infected by the injected material, and die with symptoms identical with those of typhoid. Anthrax bacilli injected in large quantities disappear within four hours, but within from twenty to forty-four hours they again appear in the blood, and the animal dies. In the period in which it is free from bacilli the blood contains, as far as the negative injection experiments show, no material producing anthrax; this is the best proof that it is the bacilli that produce the disease. In the same period, however, in which the blood is free from bacilli, in the internal organs (spleen, liver, kidneys) they are constantly present, from which it is evident that the pathological development of anthrax does not take place in the blood, but in the internal organs. Anthrax is not a blood disease, but the blood is rather the protector of the organism against the pathogenic bacteria. A very small quantity of anthrax material is not lethal, and further, the rapidity with which the disease is fatal is in direct proportion to the quantity of injected material. According to von Fodor, the bacilli injected into the blood are destroyed by it; some, however, reach the organs and there develop. When the colonies steadily multiply in these parts, then the blood, the chemical constitution of which is changed thereby, and is no longer able to

destroy the bacilli that are present in it, in this stage bacilli are found in the blood, but the animal is then practically at the point of death, its doom is sealed.

Mortality in Public Lying-in Hospitals of Germany.

Dohrn, in *Zeitsch. f. Geb. und Gyn.*, p. 121, 1886, draws attention to the great diminution in the mortality of lying-in women which has taken place in the above-mentioned establishments since the introduction of antiseptics. He selected the period of 1874–83, since in 1874 antiseptics were scarcely used anywhere, while in 1883 they had become very general. The total number of cases of labor was 104,287, and 1429 women, or 1.37 per cent., died. The vast improvement indicated by this percentage will be clear on comparison with the statistics of previous years. Thus, in 1866, Lefort found the average mortality in the lying-in hospitals to be 3.4 per cent., while Winckel, in 1869, calculated the mortality on 500,000 births to be 3 per cent. Even this great improvement, however, in lying-in institutions leaves their mortality far behind that of women attended in private practice; in the latter the percentage of deaths is only .6 to .7 per cent. Various influences contribute in bringing about this result:

1. The large proportion of primiparæ in public lying-in hospitals, puerperal fever being, as is well known, unusually common after a first confinement.

2. The clinical instruction given in public hospitals, which is invariably accompanied by special dangers, in spite of every precaution.

3. The numerous complicated cases that are sent to such establishments.

4. The fact that many women are admitted who have been examined and exposed to septic infection before admission.

Dohrn further investigated the question as to how the mortality was affected by the clinical use made of various lying-in hospitals, and he found that the mortality in those in which no instruction was given was .56 per cent.; in those where midwives were trained, 1.13 per cent.; in those where midwives and students were trained, 1.42 per cent.; in those where students were trained, 1.90 per cent. This shows, as Semmelweiss pointed out long ago, that students, who are much in contact with septic matters, are a great source of danger to lying-in women, even more so than midwives. Dohrn is of opinion that the recent decreased mortality in public maternities is solely due to the introduction of antiseptics, and that the mortality will be low in proportion to the conscientiousness with which the antiseptic system is carried out.

Hæmaturia and Granular Kidney.

In the *Brit. Med. Jour.*, Mr. Anthony Bowlby presents a paper containing the records of three cases of hæmaturia in connection with granular kidney. The first was that of a man, aged 73, who was admitted into St. Bartholomew's Hospital, suffering from enlargement of the prostate and hæmaturia. His death, which occurred within twenty-four hours, appeared to be chiefly due to the exhaustion caused by the loss of blood. A *post-mortem* examination showed an enlarged prostate and dilated bladder, containing several ounces of almost pure blood. The kidneys were small and granular. Their pelves and the ureters contained blood, and in the renal substance there was much blood extravasated. Microscopical examination showed that the hæmorrhage had occurred both into the renal tubes and into the cellular tissue of the gland. The second case was that of a man, aged 49, who had long suffered from stricture of the urethra and difficult micturition, and who, for three months previous to admission into St. Bartholomew's Hospital, had passed considerable quantities of blood with his urine. He had many of the ordinary signs of interstitial nephritis, and, in addition, passed a great deal of blood. On his death from uræmia no cause of hæmorrhage was found, except in the kidneys. These were small and granular, and contained a little bloody urine. In the third case, a man, aged 64, was admitted on February 3d, 1886, with profuse hæmaturia, and pain in the loins. After losing much blood for several weeks, the hæmaturia ceased. The urine when clear contained albumen. There was some albuminuric retinitis, and some opacity of one lens. Attention was drawn by the author to the fact that the subject of hæmaturia in connection with granular kidney had received little attention, and that no cases of profuse hæmaturia of this nature had been previously recorded, and that no *post-mortem* examinations had been described. It was pointed out that in one of the patients referred to in this paper the hæmorrhage was so profuse as to be mistaken for vesical bleeding, and in others that the diagnosis had to be made from other of the more recognized causes of renal hæmorrhage, especially calculus. It was in connection with this question of diagnosis that these cases

were of importance. Lastly, it was stated that simple interstitial nephritis, independent of dilatation or absorption of the renal substance, was often found as the result of obstruction to the outflow of urine.

Mogiphonia.

At a recent meeting of the Berlin Medical Society, Professor B. Fraenkel described a rare form of vocal failure, which he proposed to call "mogiphonia" (*μόγις*, with difficulty). He related some cases, including one male and three female professional singers, a governess, and a clergyman. One of the female vocalists was a plump rosy girl, of whose artistic future the highest expectations were formed. Her temperament was much less nervous than is usual in the case of singers, and her throat, on examination with the laryngoscope, showed nothing but slight catarrh of the mucous membrane. The larynx was well formed, and its movements, both in phonation and in respiration, were perfectly normal. When asked to sing, she began in a powerful and melodious soprano tone, but after a little time the voice seemed to lose volume, and it evidently became increasingly difficult for the singer to produce it, until finally she could not utter a note, and even the attempt to do so caused pain in the larynx. Meanwhile, the speaking voice was quite natural and free from huskiness. The other cases were of much the same nature, all the patients being healthy, and in particular having, so far as could be seen, nothing the matter with the larynx. In none of them was there the least sign of hysteria, or nervous affection of any kind. Professor Fraenkel failed to do much good by treatment; even the direct application of the electric current, both continued and faradic, was ineffectual. In one of the cases, however, some benefit seemed to be produced by massage of the larynx. After inunction of the neck with lanolin, he grasped the larynx firmly with both hands, and rubbed from above downwards on each side from forty to fifty times. There was a marked improvement after a few days of this treatment, and in six weeks the patient declared himself completely cured. Dr. Tobold said he had had good results in similar cases from the application of the constant current. It was necessary, however, to continue it for six or nine months. Dr. Krause stated that he had successfully tried a plan sometimes used by singing masters. The patient was directed to speak "into the mouth" instead of in the ordinary way. By this means, the larynx, after a time, recovered its natural power.

The Removal of Foreign Bodies.

Before an English medical society, Dr. Cleaver related the case of extraction of a halfpenny from the œsophagus of a child, æt. 3, twelve days after it had been swallowed. The child had swallowed the coin whilst playing, and on being called in, Dr. Cleaver could discover no symptoms of œsophageal obstruction. Fearing copper-poisoning, treatment was adopted to counteract such a result. Next day the child seemed quite well, and was playing about as usual. Watching the child carefully, Dr. Cleaver thought he noticed a peculiarity in the child's manner of swallowing, especially when swallowing his own saliva. Making a digital examination, he thought he could feel the edge of the foreign body, but efforts then made failed. Subsequently, after repeated attempts, the coin was secured and withdrawn with the aid of a long pair of curved forceps. The case shows the absolute necessity of a careful search being made in all cases, even when there are no symptoms indicating the presence of a foreign body. The halfpenny in this case lay across the œsophagus, its head and tail pointing anteriorly and posteriorly, and its edges right and left; its location was about on a level with the second rib.

Dr. Bartolome, in the course of some remarks made upon Dr. Cleaver's case, related how he was once asked by one of his colleagues to make a rectal examination, and to say what he thought the foreign body was which was present. On passing his finger up the bowel it came in contact with some sharp points, which proved to be the prongs of a fork which had been swallowed some time before by the patient. Colotomy was performed, and the fork removed successfully. He also related the case of a girl who had swallowed a pin. No medical man could discover its presence, and the girl was in despair and threatened to drown herself. Dr. Taylor, of Hathersage, under whose care she fell, bethought him of a little girl who had a very small hand and arm, with long taper fingers. He got her to pass her hand down the œsophagus, with the result that she discovered and withdrew the pin. Had she been able to do the same for the man colotomy might have been dispensed with.

Cocaine in Acute Gastritis.

Dr. J. Emmet O'Brien, of Scranton, Pa., relates to the *Medical Record* the case of a young girl who, after an unsuccessful attempt at suicide by laudanum, mixed a box of "Rough on Rats" in water, and drank an unknown quantity of it at intervals during

a half hour. When first seen she was in frightful agony, and the diagnosis of arsenic poisoning being quickly made, the stomach was emptied by ipecac and sulphate of zinc, and large quantities of dialyzed iron and lime-water were given. Dr. O'Brien gave two grains of morphine hypodermatically in divided doses during the night, and kept the woman anæsthetized by means of chloroform and ether for twelve hours. When conscious, the patient would take nothing unless assured that it was poison. Whenever the anæsthetic was withdrawn the patient would try to dash her brains out, and tore at her abdomen, raving about her stomach. Three persons could with difficulty hold her when not profundly under the influence of ether. Twelve hours after the poison had been taken the girl was still in terrible agony, and showed signs of collapse. On the suggestion of Dr. Gunster, over half an ounce of a four per cent. solution of cocaine hydrochlorate (about ten grains of the drug) was then administered, the supposition being that all the arsenic had been vomited or neutralized, and that gastritis was now the condition calling most loudly for relief. In a few moments the patient ceased to complain of her stomach. The mania subsided, and the patient became controllable, so that it was possible to discontinue the anæsthetic. The pulse, which had been failing, grew stronger, and the woman was soon able to walk with assistance. The mania and hallucinations continued in mild form for some hours. The patient was removed to the Lackawanna Hospital, where brandy and digitalis were given, and she recovered completely. According to the analysis of Mr. Lorenz, an apothecary of Scranton, "Rough on Rats" contains sixty-five per cent. of arsenic. Another girl, who afterward took some of the same preparation, died within a few hours. The treatment in this case was not known.

Salol in Articular Rheumatism and Acute Febrile Diseases.

Salol, the new antipyretic remedy, has been tried by Dr. Herrlich (says the Berlin correspondent of the *Brit. Med. Jour.*) in acute articular rheumatism, endocarditis, typhoid fever, and diphtheria, with good results. Salol, which is a compound of carbolic acid and salicylic acid, may be presumed to have powerful antiseptic and antizymotic properties, and may, therefore, be expected to prove useful in infectious diseases. It is decomposed in the intestines into its two constituent principles, and its action is interesting chiefly in relation to the effects of the carbolic acid thus set free within the system. Drs. Herrlich states that he has cured several cases of acute rheumatism with salol. There were, however, occasional relapses, and the treatment did not prevent the occurrence of endocarditis in some instances. The remedy was tried in eight cases of typhoid fever, and in several cases of diphtheria. Patients suffering from typhoid did not bear the remedy so well as those affected with rheumatism. Gastric complications were relatively frequent, and it was found that the best results were obtained in recent cases where the nutrition was still but little impaired. Dr. Herrlich did not find that salol reduced the temperature either too much or too quickly; it did not produce excessive diaphoresis, nor had it any bad systemic effect, with the exception of the gastric disturbance already referred to, and this was observed only in patients in a very weak condition. Carbolic acid poisoning occurred in a woman suffering from chronic articular rheumatism, who had taken 24 grammes of salol in three days. She vomited almost incessantly for eight days, and her urine contained a considerable amount of phenol. She had also much pain and difficulty in passing water. Similar urinary troubles were observed in another case. Salol, however, appears to be beneficial in certain affections of the bladder; urine which contains phenol is aseptic, and remains sweet for a long time.

Paralysis of the Left Leg from Sub-Cortical Disease, with Cancer and Fracture of the Left Femur.

Before the Clinical Society of London, Dr. Hughlings Jackson read a paper on this case. A woman, aged 52, was admitted December 28th, 1885, under Dr. Hughlings Jackson's care, for paralysis of the left leg, which had come on suddenly on December 7th, whilst she was standing at her work. The knee-jerk on the paralyzed side was greatly exaggerated, and there was foot-clonus; there was no defect of sensation; no morbid changes existed in the fundi. On December 30th, whilst she was being lifted from the bed-pan, the left femur broke just below the great trochanter, and she died on January 10th. At the necropsy, in addition to cancer of the left femur and of the ovary, Dr. James Anderson found growths in the brain, one accounting for the paralysis in the region of Ferrier's leg-centre. Schäfer and Horsley had shown that the marginal gyrus is part of the leg centre. The President said that it was interesting to note that the

patient died in little more than a month after the occurrence of the paralysis, and yet the exaggerated ankle-clonus and ankle-jerk had been remarked, although this was generally supposed to result from descending degeneration which could hardly have taken place. Dr. Beevor said the case was of interest as showing the localization of the leg-centre. The posterior part of the marginal convolution was part of this centre. The absence of fits was also remarkable. Mr. Horsley and he were carrying out experiments by stimulating the internal capsule, and they had found that the hindmost fibres went down to the leg.

The Organism Producing Decomposition of Urine.

Though it has long been known that the ammoniacal decomposition of urine is due to the splitting up of urea into ammonia and carbonic acid, by means of an organized ferment, the characteristics of this organism have not been accurately described. Many years ago Pasteur and Cohn described a *micrococcus ureæ*, and last year Leube and Graser mentioned four organisms which had the power of decomposing urea into ammonia and carbonic acid. One of these was called by them *bacterium ureæ;* the others were a micrococcus and two species of bacillus. Dr. Robert Smith has lately published the results of his work at the Brown Institution, confirming Pasteur's and Cohn's discovery of a *micrococcus ureæ*. Many kinds of organisms, as is well known, grow in ammoniacal urine, but by the modern methods of "fractional cultivation" and "dilution" Dr. Smith has separated them, and tested the action of each in decomposing urea. He found that the only organism which possessed this power, was a micrococcus occurring singly, or sometimes as diplococci, and growing in gelatine in minute dots. This micrococcus differs from that described by Leube and Graser in its property of liquefying gelatine during its growth. It may be the same organism as that described by Pasteur and Cohn; but, as these observers had not the advantage at the period of their investigations of the method of cultivation on gelatine, this point cannot be decided.

The Physiology of Opium-Narcosis.

M. Liebermann, in a monograph upon opium-poisoning, states the conclusion that the deep narcotic sleep of opium is due to severe cerebral congestion.

Reviews and Book Notices.

BOOK NOTICES.

A Text-book on Surgery, General, Operative, and Mechanical. By John A. Wyeth, M. D., etc. 1 vol., large 8vo., sheep. Pp. 777. Illustrated. New York, D. Appleton & Co., 1887.

This handsome and extensive treatise by one of New York's best-known surgeons will, without doubt, take rank among the most popular American text-books. We do not note in it any special novelty of arrangement, but the disposition of the various branches of the subject is judicious, and reveals a firm grasp on the whole of the art. The modern improvements are fully set forth, but not in the spirit of the novateur. What especially will impress the reader on first opening the volume are its fine type, numerous and excellent illustrations (a number of them colored), and the clear arrangement of the text. We predict for the work a successful sale.

A Compend of Surgery for Students and Physicians. By Orrville Horwitz, M. D., etc. Third edition, with 91 illustrations. Cloth, 12mo., pp. 203. Philadelphia, P. Blakiston, Son & Co.

We have here another edition of one of the series of "Quiz-Compends," issued by Messrs. Blakiston & Co. They have evidently filled "a long-felt want," as we may judge by the sale of several editions. The present volume is a very well prepared cramming scheme for the surgical student.

The Nursing and Care of the Nervous and Insane. By Charles K. Mills, M. D., etc. Cloth, 8vo. Pp. 147. Philadelphia, J. B. Lippincott & Co., 1887. Price $1.00.

The publishers of this work issue a series of manuals of nursing at the uniform price of one dollar each. The present member of that series is by one of the ablest, best-known specialists in our country, who has devoted his attention to diseases of the mind and nervous system. Some time since he delivered a course of lectures on nursing in such diseases before several training-schools for nurses, and the present volume is a reduction of these lectures to book form. They treat of such topics as the management of epileptics, sleeplessness, delirium, the alcohol and opium habits, and the care of the actually insane. In addition to this, we find plain, practical directions about massage, the movement cure, baths, clinical thermometer and the administration of the various of electricity. A number of illustrations are inserted, and the volume is neatly manufactured.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

IN HOW MANY WAYS DO WE HEAR?

Sound is a sensation caused by rapidly succeeding to-and-fro motions of the air, which touch points in the auricle, are reflected, touch the canal of the ear, and are then concentrated on the drum or membrana tympani. Back and within this membrane is a delicate portion of bone, termed the handle of the malleus or hammer. Fitting into this upper end or head of the hammer is the incus, or anvil, united by a cog-like joint. The third bone is termed the stapes, or stirrup. This last bone, which is the most delicate and also the most important in its relations to every other bone, may be lost, and the drum-membrane gone, yet hearing will remain. It is attached to an oval membrane, which covers a depression in the bone, termed the oval window, being very movable, the membrane is larger than the foot of the stirrup.

The oval cavity is termed the vestibule, and from it proceed three small openings called the semi-circular canals. Forming a part of this complex yet beautiful apparatus, there is a cavity to which has been given the name of the cochlea, from its resemblance to a snail's shell. The cavity of the inner ear is filled with a liquid, in which are spread out the delicate fibres of the auditory nerve, or nerve of hearing. This nerve is the portio mollis of the seventh cranial or head nerves. As its Latin name indicates, it is very soft and impressible, and also liable to injury from many causes. It arises from the medulla oblongata, and the fourth ventricle of the brain enters the internal auditory canal, and is distributed to the labyrinth on a membrane within the bony cochlea. It is lined with epithelium of a velvet-like nature. A portion of this is termed the organ of Corti, and receives the termination of the auditory nerve. This organ of Corti consists of two rows of rod-like bodies, named the rods of Corti, and several rows of ciliated cells.

Sound is conducted to the membrana tympani, touching it with a delicate or powerful touch, being transferred to the chain of bones or ossicles. These movable semi-solid bodies vibrate, and carry the sound-waves to the fluid of the internal ear by means of the foot-plate of the stapes or stirrup, where they touch the fibres of the auditory nerve, being conveyed to the centre of hearing in the brain.

These differences in vibrations make sounds higher or lower in pitch, loud or soft, simple or compound. Infinitely more complex are the vibrations produced by an or-

chestra with a chorus of human voices and solo singers associated. The mind fails in the effort to grasp the wave form of the flood of complex vibrations that pours into the ear at every moment. The highest and lowest tones are heard; the qualities of the notes produced by the strings and wind instruments and the voice are all discernible. The theory offered by Helmholtz in explanation of this wonderful property of the sense of hearing is that the terminations of the nerves in our ears can analyze complex vibrations. It was maintained by Helmholtz and others that in the ear every audible tone throws into sympathetic vibration one or more of the nerve terminations, and that all complex tones are analyzed by them into simple pendular vibrations, which affect different nerve terminations according to their frequency of vibrations.

Although this theory is at the present day doubted by some careful observers, among the number Dr. W. Rutherford,* Professor of Physiology of the University of Edinburgh, it has the acceptance of many able physicists. L. T.

PROGRESS OF THE CHOLERA.

The declaration on March 31st of a quarantine against cholera at El Paso, Texas, is a warning of the early possible approach of the much dreaded pestilence. It arrives by the usual lines of trade direct from Buenos Ayres where it reached this continent, via Chili.

The government has published some advices as to its prevalence in the last named country. The United States minister to Chili, in a dispatch dated January 15th, states that "Cholera is slowly extending along the valley of the Aconcagua, following the course of the river towards the sea, near Valparaiso. About 600 cases have so far been reported, of which about 250 have proved fatal. The victims are almost exclusively confined to the poorer classes of people. Every precaution possible has been taken by the authorities to check the spread of the disease, and stringent sanitary measures adopted, especially in the cities of Santiago and Valparaiso, which for the last month show a death-rate less than has ever been known at this season. The following dispatch from Iquique, dated January 5, appeared in the press: "The Peruvian Government has decreed to take active measures against the cholera, and has ordered the closing of all the ports against vessels coming from infected countries."

This very extraordinary and premature action of Peru, in closing all her ports against vessels from the ports of Chili, with its vast line of sea-coast of over 2,500 miles in extent, and stretching along the Pacific from Arica, on the borders of Peru, to Cape Horn, because cholera appeared in a section of Chili, midway between the points mentioned, has been severely criticised. The despatch adds: "All the steamship lines have been withdrawn from the route between here and Panama, so that the Pacific from Panama to Cape Horn is practically closed to our commerce and communication by steam. All the traffic and commerce from this coast have now to go to Europe, and this dispatch will leave Valparaiso on the 18th instant for Lisbon, thence by rail to Paris and Calais, thence by Liverpool to New York, and will probably take fifty days in transit."

At Callao the United States consul, in his dispatch dated February 19, 1887, states that no cases of cholera have appeared in Peru. The latest official intelligence is contained in the following cable messages from Santiago, dated February 15th, and from Valparaiso, under the same date: "*Santiago.*—From Saturday to Monday noon, 435 cases and 213 deaths. It is difficult to obtain exact data." "*Valparaiso.*—I have visited the lazaretto, established on the Baron hill. Seven cholera patients. Freight from Santiago enters free. Passengers quarantined for twenty-four hours." The minister reports that the health of Lima and Callao is exceptionally good. Strict sanitary precautions and hygienic regulations are still observed.

A NEW METHOD IN CASES OF POISONING.

It is a well known physiological law, that all the substances entering the animal organism, whether they are innocuous or dangerous to the existence of the individuals, are eliminated by the kidneys. Another well established law is, that the vascular system may be extended without local or general morbid changes, by fluids injected into it, if the quantity of the injected fluid amounts to about 8 per cent. of the weight of the body. When such indifferent fluids are injected in the quantity mentioned, the vascular pressure is increased; but this increase at once ceased, when the natural ways of elimination, especially, however, the kidneys, by their function carry off the fluid thus injected.

Basing his experiments on the facts

* The Sense of Hearing, British Ass. Meeting, Birmingham, 1886.

quoted, Dr. S. C. Sanquirico in Sienna, (*Ctbl. d. Med. Wiss.*, 21–87), has endeavored to determine, whether fatally poisoned animals might be saved from the impending death, when in the manner indicated, viz., by injection of indifferent fluids in a quantity corresponding to 8 per cent. of the bodily weight, a sudden increase in the urinary secretion and with it a rapid elimination of the poison is effected.

The poisonous substances used by him were alcohol, strychnine, and aconitine. S. first found out the weight of the animal, generally a dog, then he prepared a watery solution of chloride of sodium, and injected a quantity corresponding to 8 per cent. of the animal experimented upon, into the jugular vein. Whenever the poison was a rapidly fatal one, the injection was practiced immediately after the introduction of the intoxicating substance, while in cases where the action of the poison, as with alcohol, was slower, the injection was made as soon as the first symptoms of poisoning developed.

In every case the fatal end was prevented. A greatly increased urinary secretion always was the first effect of the injection, and followed it almost immediately, while the presence of the poison could be demonstrated in the urine thus excreted. The only substance that proved inamenable to treatment was muriate of aconitin; here the injection of the solution of chloride of sodium was not followed by increased discharge of urine, so that the occurrence of the latter must be looked upon as a favorable omen. To prevent mistakes S. always first determined the minimum dose of the poison sufficient to cause death, then this dose, slightly augmented, was introduced into the system, and afterwards the solution of chloride of sodium injected. The result always was a favorable one.

Notes and Comments.

An Infectious Form of Broncho-pneumonia.

At the Société Médicale des Hôpitaux M. Sevestre recently read an interesting paper on a form of infectious broncho-pneumonia of rheumatismal origin, observed in insufficiently fed children at the Hôpital des Enfants Assistés. During the first, the apyretic period, of this affection, there was gastro-intestinal disturbance and fœtid diarrhœa. In the second period, fever, occasional vomiting, dry but rare cough, dyspnœa, crepitating and subcrepitating râles, succeeded by souffle and localized crepitating râles. Two forms of this affection may be distinguished—one benign, and of rare occurrence. In the more frequent form the broncho-pneumonic symptoms are accompanied by dryness of the tongue and serious typhoid symptoms; simple erythema or pemphigoid vesicles are sometimes observed on the skin; in this case death generally ensues. Necropsy reveals red patches in the large and small intestines, marked tumefactions of Peyer's patches in the small intestine. The mesenteric ganglia are congested; there is occasionally hæmorrhage. Nuclei of broncho-pneumonia with dilatation of the lymphatics are detected; the bronchial ganglia are congested. The liver has undergone fatty degeneration, especially in the region of the sublobular veins. M. Sevestre is of opinion that intoxication by fæcal matter is the cause of the broncho-pneumonia and the infectious symptoms. He prescribes calomel at the outset, and subsequently naphthaline. M. Hayem considered that if the blood of the children were examined in order to discover if there was an increase of blood-fibrine, it might be decided whether this broncho-pneumonia was simple phegmasia or infectious pyrexia.

Napelline in Facial Neuralgia.

M. Grognot reports the following case of facial neuralgia in which napelline produced very successful results. On January 20, 1882, the author was called to see a young girl suffering from severe pain extending over the entire head, which felt, she said, 'as if it were pressed in a vice.' The pain, however, was greatest on the right side in the parietal and frontal regions, and immediately above and below the eye it attained its maximum intensity. There were no tears, but, according to the patient, there had been in previous attacks. The tongue was slightly coated, but there was no caries of the teeth on the side affected. The author prescribed one granule, containing 2½ milligrammes of napelline, every two hours. On the first day the patient took ten granules; during the evening the pain disappeared. Although the pain had not returned the next morning, the patient was advised to take four granules and two the following day. Two months later the patient's neuralgia reappeared, and she took eight granules. The next day he found the neuralgia had disappeared, and since that time the health of the patient has been excellent. Two reasons caused the author to publish his observation: first, the oblivion in which this excellent medicine seems to have fallen;

second, the fact that napelline may succeed where crystallized aconitine fails. In the above case the latter medicine had been administered without success, while napelline had produced complete and durable results. The author attributes the superior efficacy of amorphous aconitine over the crystallized drug to the presence of napelline in the former.

Treatment of Constipation by Abdominal Massage.

At a recent meeting of the Société Médico-Pratique, M. Berne described the following case of constipation successfully treated by abdominal massage:

The patient, a woman, aged 42, had suffered from constipation for several years. Her general health was very unsatisfactory. She was extremely emaciated and yellow; her tongue was coated, and she experienced a heavy sensation in the stomach. She suffered from lassitude, palpitation, insomnia, and disgust for food. The stomach, which was much dilated, gave on percussion a flapping sound. There were also regurgitations and fœtid odor. After nine massages had been performed the bowels acted freely, the patient's color improved, and she was ultimately completely cured. Details of several other cases successfully treated were given. After kneading the abdominal tegument and muscles, a slight pressure is brought to bear on the cæcal region by means of the palm of the hand; then with the clenched fist a deep massage of the colon is effected. Slight pressure on the gall-bladder, in the author's opinion, is advantageous, but not if gall-stones exist. The patient must not be pregnant, nor be suffering from tumors or inflammations of the neighboring organs. The bladder should be empty. Massage should be daily practiced from fifteen to twenty minutes at the beginning of treatment. The gentle pressure on the gall-bladder constitutes the author's modification of the Dutch and German methods, favoring the flow of bile towards the intestine.

Aspiration of the Stomach in Drunkenness.

In the *Dublin Jour. of Med. Science*, January, 1887, Mr. George Foy relates the following case:

One night in November, 1884, he was called to a man reported to be dying. He had taken a large quantity of whisky and claret, and for two hours his drunken companions had been trying to rouse him, but had totally failed. When seen he was quite insensible; extremities cold, face livid, pupils widely dilated, respiration and pulse almost imperceptible. Treatment was commenced by opening the median-basilic vein of the left arm, when, by rubbing the forearm briskly, the blood gradually flowed until sixteen ounces were drawn off. In the meantime the fine trocar of an aspirator was pushed through the abdominal wall in an upward, backward, and outward direction, just at the sternal end of the eighth rib. The canula was attached by the ordinary method to an exhaust bottle, and on turning the cock a stream of claret-colored fluid flowed into the bottle. Very soon the heart commenced to beat; the pulse was readily felt at the wrist, respiration recommenced. The canula was then withdrawn, and a stomach-pump was used to wash out the stomach. Very soon the man was able to speak, and soon recovered. The author saw no good in giving apomorphia in this case, as it has no emetic action when sensibility is quite deadened, while the respiration was too feeble to allow a stomach-tube to be introduced; so that there seemed no chance for the patient unless aspiration was attempted.

The Transmission of Cholera from Mother to Fœtus.

Lizzoni and Cattani, of Bologna, have recently published a careful examination of a five months' fœtus, which was expelled by a woman suffering from cholera. On the third day of illness, the mother aborted after the reaction stage of the disease had lasted twenty-four hours. The fœtus was examined twenty hours after expulsion, and was found to be in good condition. A *post-mortem* examination showed dilatation of the right side of the heart, with fulness of the veins of the thorax, and some bloody exudation in the pleural cavities. The contents of the small intestine were red in color, while those of the large were green. These contents were carefully removed, as well as some of the blood of the right side of the heart, and microorganisms carefully sought for. A small number of micrococci and bacilli were found in all the specimens prepared; as well as small bodies, somewhat larger in diameter than comma-bacilli, but resembling very closely an old cultivation of these organisms. No definite comma-bacilli were seen in the blood, exudations, or the contents of the intestine; but by means of plate-cultivations, colonies of Koch's comma-bacilli were grown, having their definite characteristics. From this case, as the authors conclude, it is evi-

dent that the transmission of cholera from the mother to the fœtus takes place by means of the blood. A further communication on the period of the disease when such transmission takes place is promised, and may prove of great interest.

The Alleged Prevalance of Anæmia among Miners.

The *Gazette des Hôpitaux* publishes notes of a communication made by Dr. Paul Fabre to the Société de l'Industrie Minière concerning anæmia among miners. M. Fabre, whose practice lies among the mining population of Commentry, has proved that in anæmic miners the number of blood-corpuscles and the quantity of hæmoglobin contained in them are normal. Dr. Fabre's observations at Commentry were confirmed by those which he made among the miners at Saint Etienne, Pas de Calais. The rare cases of anæmia seen among them were chiefly due to traumatic hæmorrhage, over-exertion and muscular exhaustion, alcoholism, helminthiasis, lead-poisoning, marsh fever, etc. As regards helminthiasis, M. Fabre has frequently observed among the miners at Commentry tape-worms, thread-worms, and round worms, which may have often caused anæmia; but he has never met with the ankylostomum which is generally supposed to be present in miners' anæmia. M. Fabre agrees with M. Dransard and others in thinking that anæmia is not more frequent among miners than among other workmen, and that, where it exists among miners, it has no special characteristics, and arises from the causes which always induce anæmia.

Rumination in Man.

The patient, a child of 11, had contracted the habit of causing food to return into the mouth, in order to repeat the taste of any aliments he preferred. In order to effect this, he first recalled the taste of whatever aliment he had most enjoyed in his meal, and by contracting his abdominal muscles caused the particular aliment of which he wished to repeat the taste to return into the mouth. He occasionally repeated this action a second time. On examination, the stomach was found to be slightly dilated, but made no rumbling sound; the child was pale and rather anæmic. His parents had tried every means of curing this habit. When a young child he lived in the country, and milk was his principal article of diet. The stomach became overloaded, and regurgitations ensued; the child became accustomed to these regurgitations, which finally caused a pleasurable sensation, and the habit of merycism was thus induced. M. le Juge de Sevrais proposes to submit the patient to a course of hydrotherapy, to wash the stomach out with Faucher's apparatus, and to apply actual cautery to the epigastric region. If this case of merycism be a neurosis, age and reason should cure such an affection.

Salivary Fistula Cured by the Galvano-Cautery.

In the *Glasgow Med. Jour.*, February, 1887, Professor George Buchanan records an example of salivary fistula cured by the galvano-cautery. A lady suffered from an enormous carbuncle situated on the left side of the neck, below the ear, extending to the cheek over the parotid gland. A free incision was made, and the parts almost completely cicatrized, but below the lobule of the ear a little sinus remained, from which a small quantity of semi-purulent watery fluid exuded. For thirteen years the patient had nothing done; every time mastication was performed some drops of saliva issued from the fistula below the ear. The author saw her in October, 1886, and recommended cauterization of the mouth of the fistula. A platinum wire loop was shortened and pressed together, so that the two sides of the loop were in contact, and together were not thicker than a small probe. The wire was placed on the exact spot of the fistula before it was heated, and held firmly there whilst heated by the electric current. An eschar, the size of two pins' heads, was produced by the wire, and a fortnight later the sinus was perfectly healed.

"Amykos" in Catarrh and Gonorrhœa.

In the *Russkaia Meditzina*, No. 46, 1886, p. 793, Dr. J. J. Trusewicz, of St. Petersburg, draws attention to "amykos," an antiseptic fluid prepared in Upsala and extensively used all over Sweden and Finland. Its essential constituents seem to be boracic acid and thymol. Diluted with two or three volumes of water, amykos makes a good injection or irrigation in acute or in sub-acute coryza and syphilitic rhinitis. The author also found solutions of amykos very useful as collyria in acute conjunctivitis and as irrigations in catarrhal otitis. The best results, however, were obtained in acute and chronic gonorrhœa; the burning pain on micturition was immediately relieved, and after two or three days the discharge became mucous instead of purulent. It is well to

begin with weak injections (one part of amykos to four parts of water). After two or three days the strength of the solution may be gradually increased. In mild cases the disease was cured in about a week. When mucous discharge does not cease about that time, some astringent, such as sulphate of zinc or acetate of lead should be added to the amykos solution.

Lobar Pneumonia an Essential Fever.

In concluding an article with this title, Dr. J. S. Dorset (*Gaillard's Medical Journal*) says: "The microscope of many hundreds of diameters' power reveals the fact that bioplasts and migratory leucocytes are present in the living body, and that whole colonies of living animalcula swarm in the blood-vessels and tissues of the healthy system, trooping, so to speak, up and down arteries and veins like wild buffaloes, and keeping pace with the rhythm of the heart. Now, as abnormal temperature and function produce decided changes in the physical tissue, may not the effect of disease, by malnutrition and vitiation of cell nutriment, be the cause of the transformation of minute organisms into the bacilli found in the examination of diseased tissues, and thus lend color to the popular germ-theory of disease? Inoculation successfully performed does not prove the causative agency of such germs. Any putrid tissue is capable of starting septic fermentation, and, unless proper antiseptic treatment is adopted, may destroy life by toxic necræmia, the greater or less malignancy of the process depending upon a variety of circumstances.

The Use of the Aspirator in Retention of Urine.

In the *Bristol Med. Chir. Jour.*, Dr. Fairbanks records a case in which the use of the aspirator for retention of urine proved of great service. The patient, aged 76, had suffered for some weeks from slight trouble in micturition. On February 17, 1886, he was seized with complete retention, and was relieved for three days by catheter; then difficulty arose in passing the instrument, and the author's aid was called in. On February 22d no instrument was able to be passed, and the symptoms being urgent, the aspirator was used. For the next fifteen days the whole of the urine, with the exception of that drawn off on one occasion by catheter, was passed through the needle of the aspirator. In all the bladder was aspirated thirty-two times. After this a catheter was able to be introduced, and by degrees the patient obtained control over his bladder. From the author's experience in these cases, he never hesitates to aspirate if a catheter cannot be easily introduced when the symptoms are urgent.

Movable Spleen.

Dr. M. A. Lüken, of Cronstadt, reports (*Proceedings of the Cronstadt Marine Medical Society*, No. 2, 1886, p. 15,) an interesting case of extreme mobility of the spleen in an epileptic woman, who died at the age of 40. At the post-mortem examination, the spleen, measuring 15.5 by 7 by 3 centimetres, and enclosed in a smooth tense capsule, was found in the left iliac fossa. The hilus was connected with the centre of the greater curvature of the stomach by means of a band 9 centimetres in length and 6 in breadth, and the spleen could be easily and freely moved into every corner, however remote, of the pelvis and abdomen, without stretching the band. The splenic substance was of a dark red color, and presented numerous thin whitish strips of connective tissue. Dr. Lükin thinks that the epileptic fits of the patient might possibly have had something to do with the extreme mobility of her spleen. He says that this is the only case of the kind which he has met with in 8,152 necropsies made by him during the last fifteen years.

Glycerine in the Treatment of Acute Fevers.

Semmola prescribes glycerine diluted with water, to be taken in copious drinks during the whole day. At first 15 to 20 grammes for every twenty-four hours, dissolved in 400 to 500 grammes of water, to which are added a few spoonfuls of lemon juice or a few grammes of citric acid. The following is the formula: Pure glycerine, 300 grammes; citric or tartaric acid, 2 grammes: water, 600 grammes. Dissolve 20 to 30 grammes every hour, This solution forms a very agreeable drink, and is not displeasing even to patients affected with fever. The stomach is in no way incommoded by the medicine, which has been given in doses as high as 40 to 50 grammes per day without producing intestinal derangement. Under the influence of this medicine the quantity of urea diminishes from 6 to 7 grammes.

Stone and Cancer of the Bladder.

Especially in the cauliflower excrescences of the bladder stone formations have often been recorded. Dr. Roesener (*Münch. Med.*

Woch., 1887, p. 4), reports in detail two cases where oxalic acid concretions of considerable size were found besides carcinoma in the bladder of the patients. Judging from the probable age of the stones, R. believes that the irritation produced by the mulberry concretions gave rise to the malignant neoplasm. Of diagnostic importance in the case was the presence of numerous spindle cells in the urine, which fact caused the supposition of spindle-cell-sarcoma, but the autopsy proved their originating in the muscularis. R. also mentions, as a rarity, a third case, which concerned a patient who for 19 years had carried in his bladder a stone composed of phosphates, and weighing 5 oz. without having suffered from any decided disturbances of his general health, nor from any special local inconvenience. The stone was not encapsuled.

Renou's Method of Treating Diphtheria.

M. Barbot has applied Renou's treatment during three years with admirable success. During this period he treated fifty-one cases of diphtheria, forty-eight of which terminated favorably. The author employs fumigations. His method is to place on a petroleum stove an earthen pot full of boiling water, into which is put a tablespoonful of Renou's liquor every two hours for adults, and every three hours for children from 1 to 10 years; a constant temperature of 20° to 25° C. (68° to 77° F.) is maintained in the room, or still higher if possible. In large rooms he surrounds the patient's bed with large sheets nailed to the floor, thus forming a small room, in which a high temperature may easily be maintained. The patient's throat is never touched. The patient is nourished with roasted meat, boiled eggs, soups, milk, and good wine. Ninety-four per cent. of the slighter cases of this affection are cured by Renou's treatment.

Treatment of Malignant Pustule.

The *Paris Medical* of January 29 publishes notes of three cases of malignant pustule, described by Dr. D. Frederico Rivas, which were cured with paste composed of quinine powder and essential oil of turpentine. The first case was that of a woman suffering from a pustule on the metatarso-phalangeal joint. Various methods of treatment were tried without success. On the application of the quinine and turpentine paste the pain immediately ceased and the œdema disappeared; a scab alone remained, which came away on the fourth day. The paste was equally successful in the case of a shepherd who had been stung by a fly in the lower portion of the temporal region; intense œdema of the head and neck ensued. A third case of malignant pustule was cured by the same treatment. The powder and essence should be employed in sufficient quantities to form a soft paste, which should be often renewed, as it dries rapidly.

Gastritis in Renal Disease.

In a paper before the Société de Biologie (*Le Progrès Méd.*, No. 9), M. Pilliet described the lesions of the gastric mucous membrane in the dyspepsia of renal and urinary disease. The lesions—observed in a large number of cases of different kinds of renal disease—comprise infiltration of the connective tissue in the round and fusiform cells in groups between the glands or in bands along the vessels. The gland tubules are diminished in number, much shortened, often dilated at their lower extremity, flattened superficially, and variously contorted. The cubical or prismatic cells are ill developed, as in the new-born, and show little or no formation of Nussbaum's peptic granules. The changes are best marked in interstitial nephritis, and resemble those described by Parrot in anthrepsia, those met with in chronic alcoholic gastritis and in cirrhosis of the liver, and in gastritis of tubercular subjects.

Rupture of the Bladder.

A patient was admitted into St. Bartholomew's Hospital on the morning of March 1 (says the *Lancet*), with symptoms of a ruptured bladder, in consequence of a blow on the hypogastrium whilst the bladder was distended. The injury had been received the previous evening, and Mr. Walsham operated soon after admission. A large quantity of urine escaped from the peritoneal cavity when the abdomen was opened, and a rent about an inch and a half long was found in the bladder wall. Sutures were used, passing through the peritoneal and muscular coats only; the abdominal cavity was irrigated with a 1 per cent. solution of boracic acid, and the abdominal wound closed as after ovariotomy. The patient suffered very little shock, and passed his urine naturally without the aid of a catheter every four hours. There has been no sign of peritonitis, and he may be looked upon as convalescent.

The Action of Cocaine on the Sympathetic.

Dr. Dürdüfi, of Moscow, draws (*Vratch*, No. 7, 1887, p. 175) the following conclu-

sions from experiments which he has lately made. 1. When introduced into the circulation, cocaine gives rise to prominence of the eyeballs, and dilatation of the pupils, phenomena dependent on stimulation of the sympathetic centres situated in the spinal cord. 2. Constriction of the vessels and quickening of the heart's action are also produced, probably through stimulation of the vaso-motor centres, as well as of the accelerating cardiac centres.

Local Thermometry in Small-pox.

The *France Médicale* of January 27 publishes a note of a communication, made by Dr. Montefusco (Naples), concerning local thermometry in small-pox. This author states that in small-pox there exists, in the splenetic region, a constant increase of temperature relatively to that of the hepatic region and the abdominal walls. There is no constant relation between the local temperature of the spleen and the axillary temperature.

Bromide of Nickel in Epilepsy.

Da Costa recommends the following formulæ in cases of epilepsy. *Pills*—Bromide of nickel, 60 centigrammes; powdered marshmallow, 40 centigrammes; extract of gentian, 40 centigrammes. For twelve pills. *Syrup*—Bromide of nickel, 10 grammes; water, 120 grammes; Glycerine 15 grammes; Sugar 250 grammes. Bromide of nickel is prepared by saturating carbonate of nickel with hot hydobromic acid, filtering and evaporating to dryness in a water-bath.

Correspondence.

Forceps and Chloroform in Labor.

Eds. Med. and Surg. Reporter:

After carefully reading Dr. W. F. Mitchell's article in Reporter of January 22, entitled "Midwifery in the Country," I concluded to reply, as his experience and mine is widely different regarding some points.

However, I wish to say that I most thoroughly agree with him regarding the use of the forceps. It is my opinion that they are used at least ten times when they should be but once. The wider the experience of the physician in obstetric practice, the less liable he seems to be to find it necessary to use the forceps. They are too often used by physicians who have a morbid desire to do something that will create a sensation, and the least delay in labor affords a pretext for their use.

The careful, intelligent country physician, who has an earnest desire to do the very best thing for his patient, seldom, *very* seldom, finds use for the forceps. Of course, occasionally they are necessary, and a physician would be guilty of the grossest malpractice not to use them.

Regarding the use of chloroform, in the hands of the careful practitioner, I consider it one of the grandest remedies ever introduced into obstetric practice. Dr. Mitchell says, "it certainly retards labor in most instances." This is entirely contrary to my experience. I have used it in over one hundred cases, watching it carefully in each case for the purpose of discovering if it exerted any detrimental influences over the patient, and in not one case have I discovered any bad results from its use.

On the other hand, I am satisfied that by its use I have shortened several cases of labor. Of course it is understood that chloroform *is not* to be given to produce perfect anæsthesia, but, only to the extent of semi-unconsciousness. Administered in this manner it has no effect over involuntary muscular action, consequently has no effect over the contraction of the womb; while by its peculiar action on the mind it controls voluntary muscular action. In this manner it assists, as the patient does not so readily yield to a desire to resist the natural impulses of labor.

I have a lady in my mind who is the mother of six children, the time she was in labor was as follows: The first three *without chloroform:* the first, twelve hours; second, twenty two; third, twenty-four. The last three I attended her, and *used chloroform:* first, nine hours; second, nine; third, eight hours.

On January 21st I attended a lady in her sixth confinement. She was in labor four hours; she never had taken chloroform before. After labor was over, and I was about to leave her, she expressed her thanks for (as she said) the easy time I had given her. She said she never had had such an easy time, and always had been longer in labor. I could cite many similar cases in my practice, but do not think it necessary.

Elba, Neb. L. L. Ames, M. D.

—The present value of the Johns Hopkins endowment is said to be about $5,000,000. It yielded a net income last year of about $226,000.

News and Miscellany.

Jefferson Alumni.

The annual meeting of the Alumni Association of Jefferson Medical College was held last Monday at the College. Dr. Addinell Hewson was in the chair.

The Committee on Nomination of Officers presented the following report, which was adopted, and the secretary was instructed to cast one ballot for the following persons:

President.—S. W. Gross.

Vice-Presidents.—Elwood Wilson, Roberts Bartholow, R. J. Levis, F. H. Gross.

Corresponding Secretary.—R. J. Dunglison.

Recording Secretary.—Thomas H. Andrews.

Treasurer.—H. Augustus Wilson.

Executive Committee.—W. H. Warder, L. J. Deal, O. H. Allis, James Graham, J. M. Barton, Joseph Hearn, Henry Leaman, W. H. Webb, J. C. Wilson, George McClellan, Robert Coyle, A. K. Minnich, Joseph Van Buskirk, S. R. Stirling, T. C. Fulton, T. H. E. Gruel, J. H. Lopez, L. D. Judd, R. R. Stewart, D. D. Stewart, L. Webster Fox, Laurence Turnbull, Lee Lowengrund, James Robinson, Edward Graham.

Orator for Next Year.—Dr. Austin Flint, of New York.

The Committee on the S. D. Gross Professorship of Pathological Anatomy reported that the total amount received could not be stated, but that the faculty considered it sufficient to found the professorship, and would ask the favorable consideration of the trustees.

The treasurer reported a balance of $5,868.

Dr. S. W. Gross, the newly-elected President, took his seat and returned thanks for the honor conferred.

Obstetrics in Dresden.

Professor Leopold has recently published in the *Centralblatt für Gynäkologie* an account of the management of the Royal Lying-in Institution at Dresden from the time when he began his official work there, that is to say, from September, 1883, to September, 1886. Excellent arrangements have been made to increase the efficiency of the institution as a hospital, as a training-school for midwives, and as a school of clinical obstetrics for medical students; and provision has been made for the comfort of the resident staff and pupils, hygienic considerations not being neglected. Four thousand one hundred and twenty-eight deliveries occurred in the three years; 43, or 1 per cent., died; 20 of these, or 0.48 per cent., dying from septic infection, 13 of the 20 succumbing during an epidemic in the course of the first year; 3 of the same series were already septic when admitted. The 20 cases of death from infection were thus distributed over the three years: First year (epidemic), 14 cases; second year, 4; third year, 2. After the subsidence of the epidemic in the first winter, the strictest rules were enforced from May 1, 1884, at the same time that corrosive sublimate was introduced as an antiseptic. From that date till September 1, 1886, 3,196 deliveries took place, with 7 fatal septic cases (0.21 per cent.); subtracting 3 of these cases, which were admitted septic, 4, or only 0.12 per cent., succumbed to septic influences received in the institution. Between May, 1884, and the end of July, 1885, 1,686 deliveries without one fatal septic case occurred; this series included many very severe instrumental cases. In the total 4,128 cases, there were 463 operations (11.2 per cent.). This list includes 64 turnings, 54 craniotomies, 5 embryotomies, 29 induced premature labors, 25 detachments of adherent placenta, 33 removals products of abortion, and 15 Cæsarian sections. Puerperal convulsions occurred in 1 in 158 cases, placenta previa in 1 in 137, contracted pelvis in 7.3, and severe laceration of cervix, repaired by Emmet's operation, in 1 in 179. The forceps were used in 1 in 28 deliveries. These statistics speak highly for the value of the Dresden Lying-in Institution, both as a hospital of the greatest service to suffering women and as a rich field for clinical instruction.

After-effects of the Earthquakes on the Nervous System.

The *Lancet* says: It is curious to note that many persons who were calm and apparently not greatly disturbed by the earthquakes which recently occurred in the Riviera have since suffered seriously from the effects of shock. This fact shows, beyond the possibility of question, that more may be done in the way of injury to the nerves by an undue excitement that is at the time perceived, just as more may be done in the way of restoration to nervous health after an illness than is immediately evident. The explanation of these seemingly paradoxical effects is to be found in the fact—perfectly familiar to every student of nerve-troubles—that in a very special manner

health in respect to the nervous system is dependent upon the integrity or orderly performance of nutritive functions. Muscular tissue may be badly nourished for a time, as in the course of an ordinary illness, and as soon as convalescence is fairly established recovery of the wasted muscles will commence, use stimulating re-growth naturally, with the result of perfect recovery in a comparatively short time. It is not thus with nervous tissue, whether in brain, spinal cord, or nerve trunk. When from any cause nutrition is impaired in a nerve centre or branch, not only is there extraordinary difficulty in restoring the integrity of nervous function, but the wear and tear of ordinary life, even when these are reduced to a minimum, seem to increase the exhaustion instead of reducing it by stimulation of the recuperative faculty. The reason of this seems to be that nerve centres, like batteries, are apt to be discharged suddenly and sometimes unconsciously; and when once what may be termed the residual stock of energy is consumed, it takes a very long time and often extreme carefulness to restore this reserve. Until the loss of strength held in reserve is slowly accumulated by an excess of production over consumption, the nervous system is, so to say, working on its daily strength, and can have none of that buoyancy which is due to the existence of a stock of force which has been unexhausted. No doubt those present in the earthquakes, though calm, were subject to a severe strain, and they have not yet had time to recuperate.

A Physician's Reception.

Dr. Hunter McGuire, of Richmond, Virginia, one of the most prominent surgeons of the Southern army during the late war, delivered the annual oration before the Alumni Association of Jefferson College in the lecture-room of the College Hospital last Monday evening. His subject was "The Progress and Development of Medical Science."

Dr. McGuire graduated from Jefferson College about thirty years ago. His services during the war, and his career since then, led to his election as an associate member of the College of Physicians at their late centennial anniversary.

Dr. McGuire was introduced by the new President of the Association, Dr. Samuel W. Gross.

After the speeches, the guest of the Alumni was tendered a reception at the Bellevue Hotel, where an elaborate supper was laid in the banqueting hall, around the pillar of laurel in the centre.

"Well, well," said Dr. Sayre, as he leaned on his cane, and surveyed the as yet undemolished pyramids of ice and fruit; "you Philadelphians beat New York when it comes to affairs of this sort. I suppose this is Æsculapius," he added, as he pointed to a large figure of an ice man stirring oysters in a mortar with a pestle. The distinguished doctor was then seated in the large arm-chair, sacred to the "baby" of the Clover Club, where he shared the honors of the evening with Dr. McGuire, and received the gentlemen whom Dr. Thomas Andrews, the promoter of the reception, presented to him. Among those present were the following physicians:

D. Hayes Agnew, R. J. Dunglison, L. A. Deal, T. H. Bradford, S. Weir Mitchell, William Ashton, Addinell Hewson, Jr., Ellwood Wilson, J. Solis Cohen, S. S. Cohen, H. C. Chapman, O. H. Allis, T. G. Morton, John H. Packard, F. H. Gross, T. Hewson Bradford, Orville Horwitz, L. Webster Fox, H. F. Hansell, Theophilus Parvin, Joseph S. Neff, Stephen F. Fuguet, William Thompson, and Messrs. W. H. Warder, C. Meigs Wilson, L. T. Gruel, J. Minis Hayes, Furman Sheppard, E. H. Wiel, Frank Woodbury, Professor J. W. Holland, and W. S. Forbes.

The Feats of an Armless Man.

There recently died at Potsdam, St. Lawrence county, New York, Richard Donovan, who was in some respects one of the most remarkable men in Northern New York. Twenty years ago, when a boy, Donovan worked in a flour mill. One day he was caught in a belt and received injuries that necessitated taking off both arms at the shoulders. This misfortune did not discourage him, and after recovering his health, he set about earning his livelihood as best he could without the use of hands or arms. Part of the time he had lived alone, and from the necessity of helping himself, he became wonderfully adept in performing all kinds of work, using his feet and mouth principally. He owned a horse, of which he took the entire care, harnessed it, fastened and unfastened the buckles with his teeth, and drove with the reins tied around his shoulders. Being in need of a wagon, he bought wheels and axles and built a box-buggy complete and painted it. He went to the barn one winter day and built a cow stable, sawing the timber with his feet, and with the hammer in one foot and holding

the nails with the other, he nailed the boards on as well as most men could with their hands. He dug a well twelve feet deep on a farm in this town, and stoned it himself. He could mow away hay by holding the fork under his chin and letting it rest against his shoulder. He would pick up potatoes in the field as fast as a man could dig them. He would dress himself, get his meals, write his letters, and in fact do almost anything that any man with two arms could do.

Medical Superstition in the Highlands.

Strange as it may appear to people of intelligence, it is an incontrovertible fact that in the Highlands of Scotland, as in the Continental Highlands, a belief in miracles, and in incantations and superstitious practices of the grossest nature in curing certain forms of disease still exists, of which the following incident, occurring the other day at a village on the west coast of Ross, is an illustration: A middle-aged fisherman was seized with a somewhat sharp attack of an eruptive disease, popularly known by the name of shingles, which, according to the local wiseacres, could be cured only by an application of blood drawn from a black cat with a knife or other instrument with which the umbilical cord of at least seven male children had been divided, and applied with a feather from the wing of a black domestic hen which had hatched not less than three broods of chickens. To this sanguinary ordeal the patient, at the solicitations of his friends, agreed to submit with becoming resignation and unquestioning faith in its efficacy. Having been undressed and laid on his back with his head towards the south, operator A walked round him three times with the cat, in accordance with the course of the sun. He then held the cat over the patient's breast, while B, with the proper instrument, cropped its right ear, and as the blood trickled on the sufferer's breast, besmeared it over the affected parts with the feather from the black hen, at the same time muttering incantations in the vernacular. Strange to say, the treatment failed to effect a cure, and as the patient is still unwell, he is about to undergo a repetition of the ordeal.

How he Earned his Fee.

A doctor named Francois (says the Paris correspondent of the Philadelphia *Times*) earned a hundred francs easily the other day, and had a good deal of fun into the bargain. A lady's pet dog swallowed a bank-note of the value of 1,000 francs. It was such an accident as has happened before in the world's history, and it has usually resulted, when the amount lost was large, in the immediate death of the dog. In this case the lady would have sacrificed the bank-note rather than the innocent pup, so she set out at once for the office of her family physician, Dr. Francois. The doctor was first amused, and then puzzled. The lady was sure the dog had not chewed the note all to pieces, and she offered the physician ten per cent. if he should save it. He would have done his best to please a client, and so he tried the only remedy that seemed to offer hope. Doggy was placed in a chair and a pan was put in front of him. Then the physician administered an emetic. The dog took a whole glassful without protest and without effect, while his mistress stood by anxiously. After that the dog seemed disinclined to swallow more, but a little was forced down his throat, and then the smell of the dose became so disagreeable that what had been taken speedily appeared, and, happy to relate, the thousand-franc note was included. It was intact, and only needed a patient drying. Doggy recovered in a half hour.

Left-handed People.

The *Pall Mall Gazette* says that Dr. Louis Jobert has just published a book on "The Left-handed" (Die Linkser), in which he treats exhaustively of the class of persons who are more dextrous, if we may use such a pun, with the sinister than with the dexter hand. He says that no traveler has ever yet come into contact with a purely left-handed race, but there are some tribes which, from immemorial time have given preference to the use of the left hand. Among such tribes, however, not more than 70 per cent. are left-handed. It is sometimes the rule among such tribes to account the left-handed side, instead of the right, as the place of honor. He prints a curious appendix by Dr. Monro, who has made extensive studies of the physiological peculiarities of the criminal class. Dr. Monro asserts that he has found among condemned criminals 22 per cent. who were left-handed, while a comparative research among other persons has convinced him that the proportion of the left-handed is not above 9 per cent. This would seem a sort of justification of the moral application of the word "sinister."

Foreign University Intelligence.

Berlin.— The recent medical vacation classes have been well attended by foreign

practitioners. Out of 148 there were seven from England and Scotland, thirteen from North America, thirteen from Sweden and Norway, six from Brazil, and two from Japan.

Buda-Pesth.—Dr. David Onodi has qualified as *privat docent* in embryology.

Dorpat.—The Russian Ministry of War has arranged to give a grant of £250 to a laboratory and clinic that is about to be established in connection with the Veterinary School for the express purpose of investigating the subject of glanders.

Gottingen.—Dr. Wolfthügel has been appointed Professor of Medical Chemistry and Hygiene, and Director of the Institute in connection with these subjects in succession to Professor Flügge, who has gone to Breslau.

Leipsic.—Professor Heubner, who had at first accepted the invitation to the chair of therapeutics at Prague, has, at the urgent solicitations of his friends, decided to stay in Leipsic.

A Vampire Legend.

The *Pall Mall Gazette* says that a landed proprietor, Baron de Gostovsky, living at Sabouez, near Danzig, made the request that at his death his head should be cut off before his interment, a service which he said he had performed on the body of his wife after her death. "We are a family of vampires," he added, "and if this precaution be not taken, we can find no repose in the grave, but come back and bring misfortune to our children." The eldest son faithfully fulfilled the father's request, but notwithstanding this, he fell ill a few days after the funeral. Then he went to the cemetery, caused the grave to be opened, turned the body over and threw the head into a wood near by. Only the slight punishment of a fortnight's imprisonment was imposed upon the perpetrator of the outrage, on account of the statement of numerous witnesses that the profanation of the sepulchre had its reason solely in the firmly-rooted superstitions in Lithuanian country districts.

Lunacy in Russia.

Professor Kovaleffski, of the Kharkov University, has stated that there are at least one hundred thousand lunatics in Russia. Only one-tenth can be accommodated in asylums, where, moreover, the treatment is generally defective. The keepers are for the most part rough men, who maltreat the unfortunates if not bribed to kindness by relatives. The nourishment is insufficient and of bad quality. Thousands of lunatics who cannot be accommodated in public or private asylums are to be met with everywhere in the country, often ill-used by the heartless, and sometimes taking their revenge by setting houses on fire or mutilating children.

Another Fasting Man.

There is another fasting man, a Norwegian named Cetli, who commenced to fast on March 10, at Berlin. He is being closely watched by a scientific committee, of which Professor Virchow is said to be chairman. Perhaps the most interesting fact yet reported is that the Berlinese have discovered a new descriptive term for a fasting man; they call him a "*Hunger virtuoso.*"

Medico-Chirurgical College.

The sixth annual commencement of the Medico-Chirurgical College, of this city, was held in Association Hall on Thursday last, April 7. The degree of Doctor of Medicine was conferred upon a number of young gentlemen. The Dean of the Faculty, Dr. P. D. Keyser, delivered the annual address, while the alumni oration was delivered by Prof. Dudley S. Reynolds, M. D., of Louisville, Ky.

Epidemic of Trichinosis.

An epidemic of trichinosis is at present prevailing in the province of Leeland, in Holland. Trichinosis being unknown in Holland up to the present time as an epidemic, the disease spread for some time before its true nature was ascertained.

Personals.

—Dr. Richard J. Levis will be back from Paris about the 1st of May.

—Dr. Thomas G. Morton expects to take a flying trip to Europe this spring.

Items.

—A family of Florida natives recently passed through Gainesville, four of whom, boys from six to ten years old, were almost exactly the same size and weight. The father explained that where they came from the chills and fever were so bad that the children stopped growing when they were about six years old.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

GREEN SPRING SANITARIUM,
AND
WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten aces. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and massage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

BELLEVUE HOSPITAL MEDICAL COLLEGE,
CITY OF NEW YORK.

SESSIONS OF 1887-88.

The REGULAR SESSION begins on Wednesday, September 21, 1887, and ends about the middle of March, 1888. During this Session, in addition to the regular didactic lectures, two or three hours are daily allotted to clinical instruction. Attendance upon at least two regular courses of lectures is required for graduation.

The SPRING SESSION consists of recitations, clinical lectures and exercises, and didactic lectures on special subjects. This Session begins about the middle of March and continues until the middle of June. During this Session, daily recitations in all the departments are held by a corps of Examiners appointed by the Faculty.

The CARNEGIE LABORATORY is open during the collegiate year, for instruction in microscopical examinations of urine, practical demonstrations in medical and surgical pathology, and lessons in normal histology and pathology, including bacteriology.

For the annual Circular and Catalogue, giving requirements for graduation and other information, address Prof. AUSTIN FLINT, Secretary, Bellevue Hospital Medical College, foot of East 26th Street, New York City.

FOR SALE. An old established practice and property, of a physician wishing to retire. Price $2,600; easy terms. Address, DR. KEELER, Tannersville, Monroe Co., Pa.

A COUNTRY DOCTOR'S OBSTETRIC RECORD.

BY G. LAW, M. D.,

Of Greeley, Colorado.

(*Concluded from page* 455.)

January 3, 1881. Mrs. G. Vertex; female. Found this patient had been in labor all night (I arrived at 4 a. m.), and had walked the floor back and forth, clad only in a wrapper and in her stockings, the weather intensely cold, her house a mere shell, and very little fire in a very inferior stove. I made haste to get her into bed, with hot applications to her feet. The labor was soon over. But she contracted croupous pneumonia, extensive and severe, and barely escaped with her life.

January 6, 1886. Mrs. P., primipara, lived ten miles out in country. Her house was very small and uncomfortable. Her nurse was the mother of her husband, and was eighty years old, marvelously strong physically, but mentally wayward and imbecile. Presentation; vertex; first stage tedious and unduly painful; second stage, pains almost nil, and the patient's strength fast ebbing. Hence, I finally put on the forceps and delivered, alive, a fine, large male child. I gave ergot, and addressed myself to the getting away of the placenta. Had finally to pass my hand and peel it off in fragments. Then washed out the uterine cavity with hot carbolized water. Sewed up the torn perineum. Thoroughly washed my patient, adjusted her binder, put on clean linen, and finally left for home, quaking with terror for her future.

All appeared to go well until I was hastily called on the night of the 12th, and found her flowing so freely that I dared not trust to any save the most radical measures. Swabbed out the uterus with tinct. ferri chloridi through a speculum. No cervical tear, but a perfectly open, very flaccid uterus. These measures controlled the bleeding, but a sharp metritis, also phlebitis, ensued; ultimately septicæmic symptoms, and death on the 19th.

This was the second woman lost during my professional life at this time, numbering twenty years, less two months.

January 14, 1881. Mrs. R. Vertex; male; normal.

January 17, 1881. Mrs. N.; vertex; male; short, easy labor in every respect, but metritis and septicæmia ensued, necessitating careful attention until the 29th, when she was dismissed, practically well.

February 11, 1881. Mrs. R., primipara, vertex; female; normal.

February 13, 1881. Mrs. N.; vertex; male; normal.

March 29, 1881, Mrs. N; vertex; male; normal.

April 10, 1881. Mrs. N.; vertex; male; normal.

April 21, 1881. Mrs. W.; vertex; female; normal.

May 3, 1881. Mrs. E.; vertex; male; normal.

May 5, 1881. Mrs. S.; vertex; female; normal.

May 18, 1881. Mrs. P.; vertex; lingering second stage; forceps; recovery normal.

May 28, 1881. Mrs. W.; vertex; male; normal.

June 18, 1881. Mrs. G.; vertex; male; normal.

June 27, 1881. Mrs. M.; vertex; male; normal.

July 15, 1881. Mrs. H.; twins, both male; first vertex, second breech; second only lived twelve hours; cause of death, imperfect closure of foramen ovale; died cyanosed; mother's recovery normal.

July 17, 1881. Mrs. B.; vertex; female; normal.

July 27, 1881. Mrs. McC.; vertex; male; normal.

July 30, 1881. Mrs. P., primipara; vertex; very tedious second stage; pelvis male type; forceps; female; perineum torn; stretched; recovery perfect in every respect.

August 8, 1881. Mrs. M.; vertex; female; normal.

September 9, 1881. Mrs. B., primipara; vertex; lingering second stage; forceps; perineum torn; sutured; recovery good in every respect.

October 10, 1881. Mrs. W.; vertex; male; large; very quick labor. This patient had varicose veins in one leg; slight phlebitis developed in these; eventually made good recovery.

October 12, 1881. Mrs. W. Found this patient in the same condition spoken of at length on the preceding pages, except the liq. amnii was not excessive this time. She was excessively obese, with an extremely pendulous belly. The uterus lay with its fundus directly anterior, with the cervix pointing towards or above the promontory of the sacrum. Only that I was able, as before, to pass my hand freely into the vagina, I should not have been able to make out the presentation. Vertex; lifted the pendulous belly, and bandaged it down firmly, and required the patient to strictly keep the dorsal position, and had the satisfaction to see the labor terminate normally in a reasonable time as before. Child female; recovery normal. This woman wears an enormous Hodge's pessary year in and out, coming to me occasionally to have it taken out, cleaned, herself examined, instrument replaced. Is able to do her own work in her large family. Without this instrument she is almost helpless. She only dispenses with it during the latter half of her pregnancies.

October 10, 1881. Mrs. B. Vertex; male; normal.

October 22, 1881. Mrs. Von G. Vertex; female; normal.

October 22, 1881. Mrs. S. Vertex; female; normal.

October 30, 1881. Mrs. B. Vertex; female; normal.

December 3, 1881. Mrs. W. Vertex; male; normal.

December 15, 1881. Mrs. P., primipara. Vertex; female; normal.

December 19, 1881. Mrs. L., primipara. Vertex; male; normal.

February 9, 1882. Mrs. McK., primipara. Breech duration, thirty hours; twenty miles in the country. Had to finally bring down the feet, deliver the body, and turn it up in the direction of the mother's abdomen, and deliver the head with the forceps. Child, male; weight thirteen pounds; dead; perineum torn *through into and up the bowel two inches.* Stuffed a napkin—after dipping it in boiling water and wringing it—into vagina; placed three carbolized silk sutures in the bowel by means of a well-curved common surgeon's needle, held in a holder, left first finger in the bowel as a guide, tied and cut short; placed the vaginal sutures in the usual way; kept her bowels quiet with full doses of opium for six days, and then used enemas until they moved; union throughout as perfect as need be; recovery good in every respect.

February 22, 1882. Mrs. S., a very large and strong woman. Vertex. The most forcible, expulsive, or second-stage efforts I ever witnessed: tried to modify them by the free administration of chloroform. Notwithstanding the extreme force of the expulsive efforts and a most capacious pelvis, and no fault of position in the child; the second stage was protracted. Finally, the child, a large and finely-formed male, together with the placenta and a pailful of blood, was suddenly expelled. The child dead and completely exsanguined. The cause was a funis four inches long, abnormally thick and strong.

The placenta had been pulled from its uterine attachment before the completion of the labor, and the child had died exsanguined. Would I have saved the child if I had used forceps and delivered quickly?

February 28, 1882. Mrs. K., primipara, aged thirty-five, about the end of the seventh month. Vertex; placenta prævia; flooding frightfully; when I arrived, tried separation, hoping the head would engage, driven at length to bring down the feet and deliver child; dead; recovery good.

March 2, 1882. Mrs. M., primipara. Vertex; male; normal.

March 8, 1882. Mrs. T. Vertex; male; normal.

June 7, 1882. Mrs. E., primipara. Vertex; female; evidently somewhat premature; weight four pounds; lived.

June 15. Child born before I arrived; mother flooding rather freely; removed placenta when this ceased.

July 22, 1882. Mrs. W. Vertex; right; male; delay in second stage; forceps; recovery; normal.

This woman was the case, September 24, 1877, of breech presentation and extreme distocia, etc.

September 4, 1882. Mrs. S. Vertex; right; male; normal.

September 20, 1882. Vertex; right; male; normal.

October 4, 1882. Mrs. L. Vertex; right; male; normal.

October 14, 1882. Mrs. B., primipara. Vertex; left; very slow in first stage; lived fourteen miles in the country; recovery; normal.

November 22, 1882. Mrs. G. Vertex; right; male; normal.

December 24, 1882. Mrs. W., primipara, aged thirty-nine. Vertex; left; duration of labor four hours; no damage to perineum whatever; recovery; normal.

January 3 1883. Mrs. S; Vertex; left; male, large; duration three hours; normal.

January 7, 1883. Mrs. P.; vertex; female; normal.

January 14, 1883. Mrs. M.; vertex; female; normal.

January 20, 1883. Mrs. W.; vertex; female; normal.

January 30, 1883. Mrs. N.; vertex; male; normal.

February 6, 1883. Mrs. B.; face; female; passed head under chloroform and rectified position; recovery normal.

February 16, 1883. Mrs. P.; vertex; R.; male; normal.

March 6, 1883. Mrs. S.; vertex; R.; female; normal.

March 15, 1883. Mrs. C.: vertex; L.; male; evidently dead several days; liq. amnii enormous; recovery normal.

March 16. Mrs. N., primipara; vertex; R.; female; normal.

March 17. Mrs. B., primipara; vertex; R.; female; normal.

March 29. Mrs. F.; vertex; R.; female; normal.

April 15. Mrs. W., primipara; vertex; female; normal.

April 19. Mrs. N., primipara; vertex; L.; female; normal.

April 26. Mrs. W.; vertex; R.; female; normal.

April 26. Mrs. J.; vertex; L.; female; normal.

May 15. Mrs. G., primipara; vertex; R.; male; large; perineum torn; sutured with silk cord; united well; recovery good.

June 5, 1883. Vertex; R.; male; normal.

June 19, 1883. Mrs. W., primipara; vertex; R.; delay in second stage; forceps; removed them when the head reached the perineum; not torn; male; recovery normal.

July 2, 1883. Mrs. N.; vertex; female; sharp flooding; gave ergot, and grasped the uterus with both hands, which I was easily able to do because of the very lax abdominal walls, and compressed it until the bleeding was controlled.

July 9, 1883. Mrs. S., primipara; vertex; male. Here was positively hour-glass contraction. Finally anæsthetized patient, and coaxed placenta through the contraction by getting a finger past and drawing down a portion, then passing at another point, until all was released; recovered normally. Child: penis, prepuce rudimentary, the glans being uncovered, urethra opened beneath the glans, which was imperforate, urethra, however, perfectly patulous.

July 28, 1883. Mrs. N.; vertex; male; dead and decidedly macerated; recovered normally.

September 17, 1883. Mrs. McN., primipara; vertex; male; normal.

October 8, 1883. Mrs. P.; vertex; male; normal.

October 18, 1883. Mrs. B.; vertex; female; normal.

November 7, 1883. Mrs. B., primipara; vertex; labor very tedious; head would not engage in superior strait; waited until long after complete dilatation, and put on forceps at superior straight, and delivered; slight laceration of perineum; sutured; united; recovery good in about the normal time; child alive.

November 15, 1883. Mrs. B.; vertex; female; normal.

November 19, 1883. Mrs. L., primipara; weight 90 pounds; vertex; R.; lingering second stage; forceps; perineum torn; sutured; united; had to draw patient's urine with catheter for seven days; no rise of temperature; recovery good.

November 29, 1883. Mrs. G.; vertex; R.; female; normal.

December 4. 1883. Mrs. T., primipara; vertex; R.; male; normal.

December 13, 1883. Mrs. R., IIpara; weight 115 pounds; lived twenty miles in the country; had been in labor 48 hours when I arrived; right arm in the vagina,

with the skin pulled off it by the midwife in attendance in her efforts to deliver. Child evidently long since dead. Mother greatly exhausted. Gave her an ounce of brandy, chloroformed her, and quickly and easily brought down both feet, when I allowed her to come from under the anæsthetic, gave more brandy with ergot, and delivered the dead child, weight ten pounds, and placenta came away easily. She scarcely flowed at all, and made a quick and good recovery.

December 15, 1883. Mrs. W.; vertex; R.; male; normal.

January 7, 1884. Mrs. S. Vertex; left; female; normal.

January 14, 1884. Mrs. G. Vertex; right; male. This patient had a moderate attack of metritis, and required attention more or less constantly until February 4, when I dismissed her.

January 24, 1884. Mrs. N., primipara. Vertex; right; female; normal.

January 25, 1884. Mrs. M., primipara. Vertex; right; female; sore nipples and mastitis delayed her recovery, which, however, was eventually good; child had to be brought up on the bottle.

January 29, 1884. Mrs. C. Vertex; right; male; normal.

February 8, 1884. Mrs. L. Vertex; left; female; normal.

February 13, 1884. Mrs. F. Vertex; left; male; normal.

February 17, 1884. Mrs. W. Vertex; right; male; normal.

March 3, 1884. Mrs. T. Vertex; face anterior; forceps; recovery normal, except catherization during five days which the patient, as is her custom when needed, accommodatingly did for herself.

March 10, 1884. Mrs. N. Vertex; left; male; normal.

March 14, 1884. Mrs. R. Vertex; left; female; normal.

March 15, 1884. Mrs. B. Vertex; left; female; normal.

March 29, 1884. Mrs. N. Vertex; right; female; normal.

April 1, 1884. Mrs. J. Vertex; right; female; normal.

May 1, 1884. Mrs. J——c. Vertex; right; male; normal.

May 6, 1884. Mrs. C., primipara. Vertex; left; male; normal.

June 1, 1884. Mrs. B., primipara. Vertex; left; male; lingering second stage; forceps; normal.

June 8, 1884. Mrs. M., primipara. Vertex; left; lingering second stage; forceps; normal.

June 21, 1884. Mrs. R. Vertex; right; male; normal.

July 5, 1884. Mrs. T. Vertex; male; normal.

July 9, 1884. Mrs. T——s. Vertex; female; normal.

July 15, 1884. Mrs. N. Vertex; male; normal.

July 21, 1884. Mrs. S. Vertex; left; female; normal.

July 26, 1884. Mrs. A. Vertex; right; male; normal.

July 31, 1884. Mrs. C., primipara. Vertex; right; male; normal.

August 3, 1884. Mrs. M. Vertex; right; female; metritis and slight septicæmia; recovery eventually good.

August 3, 1884. Mrs. O.; breech; liq. amnii enormous; child male; very large head and macerated; placenta very stoutly adherent; pulled it off with my finger-nails; flooding frightful; gave liq. ergota (P. D. & Co.) hypodermically; passed a sponge wet with vinegar into the flaccid uterus; finally grasped that organ with both hands, as I could easily do, because of the relaxed abdominal walls, and compressed it until the ergot acted. She had only a very moderate metritis, and soon made a good recovery.

August 8, 1884. Vertex; L.; female; normal.

August 29, 1884. Mrs. B., primipara; æt. 40; vertex; R.; labor short and easy; child male; recovery normal.

September 8. Mrs. W.; vertex; female; normal.

September 11, 1884. Mrs. E., primipara; vertex; female; normal.

September 24, 1884. Mrs. S., primipara; vertex; female; normal.

October 9, 1884. Mrs. P.; vertex; L.; male; normal.

October 13, 1884. Mrs. M., primipara; vertex; L.; male; normal, except catheterization during three days.

October 14, 1884. Mrs. N.; vertex; R.; male; hare-lip, upon which I successfully operated when the child was one day old; the second day had to pass catheter for mother; mucous lining of bladder became impacted in the eye of the instrument; I slipped a piece of rubber tubing over the catheter, and attached a Davidson syringe, and easily detached it by pumping in a bulbful of warm water. She made a good recovery. I have not used a silver female catheter since. I take a No. 6 male rubber catheter, and cut off three inches of the distal end, attach a yard of rubber tubing to the proximal end. In using, drop the end

of the tubing into the chamber-vessel on the floor, pass the catheter, and the urine flows into the vessel. Nothing is spilled in the bed, and the catheter is only just long enough to reach into the bladder. I have not had this kind of an instrument stick fast yet.

October 17, 1884. Mrs. J., primipara; vertex; L.; male; normal.

November 9, 1884. Mrs. E., primipara, vertex; L.. male; normal.

December 5, 1884. Mrs. W.; vertex; R.; male; normal.

December 18, 1884. Mrs. R.; vertex; R.; female; normal; child had talipes varus of left foot. I instituted treatment at once, and eventually had most gratifying success.

December 21, 1884. Mrs. N., primipara; vertex; R.; female; normal.

December 22, 1884. Mrs. F., primipara; vertex; L.; female; normal.

December 24, 1884. Mrs. R.; vertex; R.; male; normal.

January 5, 1885. Mrs. C.; vertex; male; normal.

January 6, 1885. Mrs. G., primipara, æt. 21; has been subject to epileptic seizures, one a week on an average, ever since she was seven years old. Has taken bromide until the combined effects of the disease and remedies show very plainly in her mental condition. Labor exceedingly tedious; vertex; male; forceps. She recovered from the puerperal state about as soon as any one, so far as her physical health was concerned, but was scarcely aware that she had had her child until near the end of three months. The breasts filled up enormously with milk on the third day. This I forced out with a bandage, that had to be replaced daily for six days on account of its getting so soaked with the milk. The milk finally ceased to secrete. We had to dry up the milk, because her state utterly precluded the nursing of her child—a fine, healthy one. During these three months her seizures occurred daily. At the end of three and a half months she suddenly began to improve, and has been better in every respect than for years.

January 14, 1885. Mrs. B.; vertex; male; normal.

January 20, 1885. Mrs. W.; vertex; male; normal.

January 25, 1885. Mrs. S.; vertex; male; evidently a few weeks premature; meagre and poorly nourished. Her labor was evidently precipitated by an attack of facial erysipelas, that spread over and involved the entire scalp, also down the neck anteriorly as far as the mammæ. On the day of her confinement the erysipelas was at about its acme, on the sixth day with her, as it had entirely subsided by the twelfth day from the date of its appearance. She never manifested any symptoms of peritonitis, metritis, or septicæmia; but with the subsidence of the erysipelas made a good recovery.

February 1, 1885. Mrs. R. Vertex; abdomen so sore she could not bear the weight of the clothing; face flushed, and skin so hot that I was startled; temperature 103°, taken before the os was as large as a half dollar; concluded she was suffering from metro-peritonitis; ante-partum. Her sufferings were so intense that I deemed it best to conduct the labor under quite profound anæsthesia from the beginning to the end. She had been quite miserable during several days preceding the actual commencement of labor, but had neglected to call me. However, after a rather tedious labor, she gave birth to a large and vigorous female child. And I had a case of metro-peritonitis of the most grave character on hand that took a large amount of my personal attention during the next ten weeks. I have not daily notes in detail of the treatment, hence can only indicate the general course pursued. Morphia to the verge of narcotism until the inflammatory stage was past. The abdomen finally became so tympanitic as to interfere with respiration, and other functions as well, and I ventured to tap off the gas with an aspirator needle which gave so much relief, immediate and apparent, that it was repeated daily for nine consecutive days. The treatment was morphine, quinine, stimulants, food *pro se nata*. Hot turpentine stupes to the abdomen, vaginal, and occasional uterine washings with water that had been boiled, to which was added sometimes carbolic acid, sometimes iodine. I was, and am still, afraid of the mercuric chloride where it may come in contact with extensive surfaces that are in a good state to favor undue absorption. Indeed, the call for great diligence in the use of antiseptics for the vaginal canal I did not deem to be urgent in this case, as in my opinion it was one mainly of peritonitis starting ante-partum from the uterine surface. I personally did all the douching drew the urine three times a day, and sometimes oftener, taking care that the catheter was always aseptic. In due course an immense bed-sore of great depth developed exactly above the promentory of the sacrum. This was treated with a solution, potass. permang., using a varying strength. When the slough separated, iodoform freely; it eventually healed. This woman finally made a most excellent recovery.

February 3, 1885. Mrs. N., primipara; vertex; L.; female; normal.

February 16, 1885. Mrs. F., primipara; vertex; right; female; normal.

February 23, 1885. Mrs. C., primipara; vertex; male; normal.

February 24, 1885. Mrs. K., primipara. vertex; R.; male; perineum torn; sutured; healed; recovery good.

March 3, 1885. Miss S., primipara; almost an idiot; vertex; R.; female; recovery; normal.

March 17, 1885. Mrs. P.; vertex; R.; female; normal.

March 27, 1885. Mrs. N.; vertex; male; normal.

April 8, 1885. Mrs. W.; vertex; L.; female; normal.

April 22, 1885. Mrs. T.; vertex; R.; male; normal.

April 23, 1885. Mrs. G.; vertex; R.; male; normal.

April 26, 1885. Mrs. W.; vertex; male; normal. This woman was thin in flesh, and when the uterus was emptied and contracted, I could plainly feel a globular tumor in the right hypochondria on a level with the fundus uteri, in size that of a medium orange. She is still in good health, or was a few months since, when she moved up into Wyoming Territory.

May 6, 1885. Mrs. W.; vertex; left; female; normal.

May 14, 1885. Mrs. M.; vertex; L.; female; normal.

May 15, 1885. Mrs. F.; vertex; L. This labor was exceptionally severe and protracted, and for no reason that I could see save that the woman was excessively fleshy. Forceps finally, and a large female child, that had evidently been dead several days.

June 15, 1885. Mrs. P., primipara: vertex; female; normal.

June 18, 1885. Mrs. G.; vertex; male; normal.

June 30, 1885. Mrs. S.; vertex; male; normal.

July 11, 1885. Mrs. S——t; vertex; female; normal.

July 26, 1885. Mrs. W.; vertex; male; normal.

July 27, 1885. Mrs. P.; vertex; female; normal.

August 2, 1885. Mrs. B., primipara; breech; turned the head out quickly with a blade of the short forceps used as a vectis; normal.

August 11, 1885. Mrs. M.; vertex; female; normal.

August 12, 1885. Mrs. G.; vertex; male; normal.

August 20, 1885. Mrs. G.; vertex; male; normal.

August 20, 1885. Mrs. C.; vertex; female; normal.

September 4, 1885. Mrs. McG., primipara; vertex; female; normal.

September 8, 1885. Mrs. N.; vertex; male; normal.

September 8, 1885. Mrs. G.; vertex; female; normal.

September 16, 1885. Mrs. P.; vertex; male; normal.

September 30, 1885. Mrs. F.; vertex; male; normal.

October 9, 1885. Mrs. F——r; vertex; male; normal.

October 27, 1885. Mrs. W.; vertex female; normal.

November 3, 1885. Mrs. N.; vertex; female; normal.

November 3, 1885. Mrs. G.; vertex; female; normal.

November 18, 1885. Mrs. B.; vertex; female; normal.

November 21, 1885. Mrs. J.; vertex; male; normal.

November 28, 1885. Mrs. A.; vertex; male; normal.

November 30, 1885. Mrs. P,; vertex; This woman had had a deep bilateral rent in the cervix repaired two years before. I deemed it best to conduct her labor under the rather full influence of an anæsthetic. A mixture of ether and chloroform was used. Meanwhile watching the dilatation closely and anxiously, but not a drop of blood was shown until after the completion of the second stage, hence I concluded and subsequently ascertained that she suffered no injury. Made a good recovery in the normal time.

December 2, 1885. Mrs. B., primipara. Vertex; male; normal.

December 4, 1885. Mrs. M., primipara. Vertex; lingering second stage; forceps; perineum torn; sutured; united; recovered well in normal time.

December 14, 1885. Mrs. C. Vertex; male; normal.

December 15, 1885. Mrs. G. Vertex; female; normal.

December 26, 1885. Mrs. N., primipara. Vertex; male; normal.

January 1, 1886. Mrs. I., primipara. Vertex; female; normal.

January 8, 1886. Mrs. W. Vertex; male; normal.

January 25, 1886. Mrs. P. Vertex; right; male; normal.

February 5, 1886. Mrs. McC. Vertex; left; male; normal.

February 18, 1885. Mrs. S. Vertex; right; male; normal.

March 14, 1886. Mrs. L., primipara. Vertex; female; normal.

March 16, 1886. Mrs. S. Vertex; male; normal.

March 25, 1886. Mrs. N. Vertex; male; normal.

April 5, 1886. Mrs. B. Vertex; female; normal.

April 6, 1886. Mrs. G. Vertex; male; normal.

April 12, 1886. Mrs. E. Vertex; male; normal.

April 18, 1886. Mrs. K. Vertex; male; normal; feeble, with imperfectly-closed foramen ovale; died in two days cyanosed, being the second child lost by this woman in about the same way. She has very loud heart-murmurs and always develops a decided albuminuria when pregnant that soon disappears after confinement.

May 9, 1886. Mrs. F. Vertex; male; normal.

May 12, 1886. Mrs. F——r. Vertex; female; normal.

May 18, 1886. Mrs. S. Vertex; female; forceps, because of lingering second stage; mastitis; otherwise normal.

May 28, 1886. Mrs. K. Vertex; female; normal.

June 1, 1886. Mrs. E. Vertex; male; normal.

June 13, 1886. Mrs. G. Vertex; female; normal.

June 15, 1886. Mrs. T. Vertex; male; normal.

June 21, 1886. Mrs. M. Vertex; male; normal.

June 25, 1886. Mrs. L. Vertex; female; flooded badly; ergot; morphia, hypodermically; controlled. I was not called to this case early. When I arrived, I found her husband had been giving her chloroform very freely for twelve hours. She is an asthmatic cardiac variety. Labor terminated in an hour after my arrival. I am persuaded the flooding was due to the abuse of chloroform—not, however, in my hands. She finally made a fair recovery in three weeks.

June 30, 1886. Mrs. G. Vertex; male; normal.

July 8, 1886. Mrs. F. Vertex; male, seven months; dead; cause, fatty degeneration of placenta; recovery good.

July 18, 1886. Mrs. H. Vertex; female; normal.

July 24, 1886. Mrs. H——n. Vertex; female; normal.

July 29, 1886. Mrs. P. Vertex; female; normal.

August 12, 1886. Mrs. S. Vertex; female; normal.

August 13, 1886. Mrs. G., primipara; vertex; a very rigid os, with thin, paper-like edges; liq. amnii drawn off when I arrived; dilated to the size of a quarter-dollar; suffering intense; gave water hypodermically, and afterwards resorted to the warm water douche. Labor lasted twenty hours from beginning to end. Child female. This woman had no rise of temperature, did not flow unduly as to quantity or length of time; but was sleepless, could not eat. Milk came at the end of four days in scant quantity and of miserable quality, hence had to bottle-feed the baby. At the end of four weeks she was barely able to sit up. In the meantime she had been assiduously plied with tonics and peptonized foods. Still she could not be made to take sufficient food, and perforce remained weak and decidedly hysterical. Complained mostly of a lump in her throat—globus hystericus? I examined with a speculum, and found, of course, a poorly involuted uterus and a trifling tear in the cervix. She went to Denver, and is still in the hands of a specialist, who tells her that when she gets her into proper condition he will have to repair the torn cervix.

August 20, 1886. Mrs. T.; vertex; male; normal.

August 28, 1886. Mrs. W.; vertex; female; normal.

August 31, 1886. Mrs. S.; vertex; female; normal.

September 2, 1886. Mrs. R.; vertex; female; normal; child dead and acephalous; skull entirely wanting above the ears.

September 25, 1885. Mrs. A., primipara; vertex; male; normal.

October 12, 1886. Mrs. E.; vertex; L.; female; normal; child had slight talipes equinus.

October 13, 1886. Mrs. G.; vertex; male; normal. Although this woman is an incurable epileptic, she had none of her usual seizures during the two weeks of her lying-in period.

October 13, 1886. Mrs. W. Vertex; left; female; normal. Having taken care of this woman in four previous confinements, and had trouble each time with phlebitis along the course of varicose veins in one of her loins, I tried bandaging the affected leg from the hour of her confinement, and had the gratification of seeing her escape this com-

plication. Used a Martin bandage over a long stocking during the whole time she was in bed, and for ten days afterward besides.

October 23, 1886. Mrs. B., primipara. Breech; face; posterior became so tedious I had to bring down the feet; delivered the head with the short forceps. Used Schultz's method of resuscitating the nearly asphyxiated child with great satisfaction. Female; mother recovered well.

November 7, 1886. Mrs. P., primipara. Vertex; male; normal.

November 19, 1886. Mrs. M. Vertex; female; normal, notwithstanding this woman had been absolutely insane during the last four months of her pregnancy. The day after her confinement her delusions vanished; her milk came the third day; she is nursing; her child sleeps well, eats heartily; is well nourished; takes care of her child, and does most of her own house-work.

November 8, 1886. Mrs. C., primipara. Vertex; male; normal.

November 27, 1886. Mrs. R. Vertex; right; female; normal.

November 30, 1886. Mrs. G. Vertex; female; normal.

December 1, 1886. Mrs. M., primipara. Vertex; right; female; normal.

December 24, 1886. Mrs. N. Vertex; female; normal.

This completes my obstetric record during a period of thirteen years and nine months, with day and date, all done in Weld county, Colorado, amongst a pioneer people struggling with poverty and the hardships incident to the settling of a new country. When a child was born dead I have invariably said so. By normal, used in reference to the mother's getting-up, I mean there has been no rise of temperature or other complication other than mentioned, and that inside of two weeks she has been able to sit up and generally to walk about, and often to resume her usual labors and duties. I will leave all generalizing to those who choose to do so, as this report has drawn itself to such a tedious length.

EXPERIENCES IN MIDWIFERY.

BY R. P. DAVIS, M. D.,

Of Petty, Texas.

Midwifery and the forceps seem to have excited considerable discussion lately, judging from several articles which have appeared from time to time in your journal. I am strictly a country doctor, having never practiced in town or city, am isolated from other practitioners, and have to rely entirely upon my own knowledge and resources in midwifery, as well as all other branches of our profession. No doubt this very isolation has been the foundation-stone of my success in the practice of midwifery, as the following report of my sixteen years' practice in that branch will testify:

During those sixteen years I find, on examining my books, 960 cases of midwifery treated by myself, never having called in a consultant in a single case. Among that number I have attended girls as young as 13 and 14 years of age, and as old as 39 years. These two classes are generally considered fit cases for forceps delivery, but I have never used the forceps in a single one of them; in fact, I have no forceps or any other obstetric instrument, and never had, and never shall, because I have no use for them. As I have succeeded so far without them, it is reasonable to suppose that I shall never need them.

Among my cases that would be classed as unnatural, I find four breech presentations, which were tedious and slow. Two of them were in labor twenty-four hours, the other two were in labor six and eight hours. All made rapid recoveries, with no unnatural results. Had forceps been used, no one could tell what the results would have been.

I also find two arm presentations, one knee, eight foot or pedal presentations, two face, two shoulder, and two back. All the other cases were some one of the natural presentations of the head. I consider any of the head presentations except the face as being natural, or at least sufficient for natural delivery without the meddlesome interference of forceps.

I have been forced to make versions, and to aid the woman considerably, but I have always used my natural forceps or hands. I am pretty stout, have large, long fingers, and with a good knowledge of labor and its principles, I put all my cases through without instruments. Among them all there occurred not a single case of child-bed fever, or any other of the so-called puerperal diseases. But I have seen and treated several cases of child-bed fever in the practice of other doctors who had used ergot and forceps.

I consider ergot in any of its forms, when not used properly, just as dangerous and devilish as the forceps, and never use it except in uterine hemorrhage, and then I always give deodorated tinct. opium with the ergot. Perhaps the opium does the work, and would do as well or better without the ergot.

Among all my cases not a single death has occurred of the mother, and only three of the children, who were premature.

What do you think of a country doctor having 960 cases of midwifery in sixteen years of general practice and not losing a single case, or using the forceps in a single one? I will tell you my maxim and the secret of my success: Let nature take her own course and have her own time, "if it takes all summer," and when she takes a wrong course, put her right with your own natural forceps or hands, and nine times out of ten your cases will go through satisfactorily. I aid most of my cases in the first stage with chloral and potass., and the second stage with chloroform. I use a great deal of chloroform in labor, and would not do without it. I give it in all cases. They would not have a doctor who did not let them have an anæsthetic.

Medical Societies.

GYNÆCOLOGICAL AND OBSTETRICAL SOCIETY OF BALTIMORE.

(*Concluded from page* 462.)

If the indications were sufficient to call for a positive diagnosis in such a case as the one related, where the cervix was long and conical, and the os undilated, he would prefer to make a sufficient amount of dilatation with a dilator to admit of the introduction of a Barnes' bag into the cervical canal, if a sufficient amount of dilatation to admit the bag could not be procured, he would prefer to insert a tupelo or antiseptic sponge tent (covered with gold-beater's skin) and tampon behind this, and removed the tent at the end of four or six hours and introduce the Barnes' bag. The use of the tampon in this manner would not only check the hemorrhage, but soften down and produce more rapid dilatation of the cervix.

Dr. T. A. Ashby said no strict rules should be established in the treatment of placenta prævia. Each case should be treated on its individual merits, and such methods should be adopted as gave promise of the best results in the case under observation. He believed in the expectant plan of treatment until positive indications for interference were clearly presented. He fully coincided with the opinion expressed by Dr. Neale in regard to the great value of the method of Braxton Hicks, and, in those cases in which premature delivery was indicated, he believed this method gave the best results.

Dr. Williams has asked for an explanation of the cause of death in the case related by him. Dr. Ashby had no arbitrary opinion to express, but he believed that the loss of blood offered a satisfactory solution of the problem. He had reported to the Society some months ago a case of death following labor in a patient who had organic heart disease. The amount of blood lost was not sufficient in itself to have caused death, but it so disturbed the action of the heart that this organ failed to perform its duty, and death from apnœa resulted. The symptoms described by Dr. Williams resembled in many of their features those observed in this case, so that he was induced to associate the fatal result in Dr. Williams' case, in respect to its causation, with a disturbance of the heart's action dependent upon hæmorrhage. If death did not occur from loss of blood in this case, the only two conditions which could explain the result was either a heart clot or cerebral embolism.

Dr. Williams, in reply to a question by Dr. Ashby, said that before the administration of the chloroform he had examined the patient's heart and found it healthy.

He did not have any opportunity to make a positive diagnosis, as he did not see the patient until about the time that labor set in. When he first saw her he did not consider that she was in a dangerous condition, but with the history of previous hemorrhages he thought it would be safer to tampon and so protect her against any possible further loss of blood. He was sent for again in five hours, and as the pains had increased he removed the tampon. The os was only slightly open, but was *dilatable*, and on introducing two fingers he was able to feel the edge of the placenta, and could pass his fingers beyond it into the cavity of the uterus.

As he had said in his paper, he rejected verson owing to the depth and narrowness of the vagina. On applying the forceps and drawing the head down, the hemorrhage was completely controlled, and after this, practically, no blood was lost. When he left the patient after the delivery of the fœtus, the uterus was firmly contracted. He thought it possible that even the slight effort made by the patient in rising to drink might have caused syncope with the formation of blood clots which he considered the cause of death. The condition of the patient was not such as he would expect to find in a case of hemorrhage.

He had never met with but two cases of placenta prævia, and both of these were in the practice of other gentlemen, and he congratulated himself upon this exemption.

Dr. G. W. Miltenberger thought that Dr. Neale could have made his point, which was a good one, still stronger from the same statistics, which he had quoted from Lomer.

The doctor had given the general result for Hofmeier, Behm, and Lomer, which included all the cases operated upon by Braxton Hicks' method.

In this number were compiled cases treated by several assistants. Some of the women had come in moribund, some were very anæmic, some had had other operative measures resorted to previous to admission. In this mortality were included all cases dying after delivery from septicæmia.

The mortality here 21 to 236, about 10 per cent., vies with the exceptional mortality of so skilled an obstetrician as Behm of 6 in 64, about 10 per cent. When we take their cases treated by bipolar version alone, we find much better results.

	No. of Cases.	Deaths.
Hofmeier	37	1
Behm	40	0
Lomer	101	7
	178	8

4.3 per cent.

And even here Lomer's cases were treated by himself and assistants, who were just learning. If we take those treated by Lomer himself, 16 without a death, we have the unprecedented result of the three, of 93 cases with one death.

This is truly startling, and there is nothing in this generation which can compare with it.

They do not advise that other means should all be abandoned, for in case of head presentation with marginal placenta, if pains are strong and hemorrhage slight, head having entered the pelvis, rupture the membranes, and if needed, forceps will suffice.

But in the great majority of cases, this method surely offers more than any other which has heretofore been employed.

Dr. Williams asked permission to say a few words in closing the discussion of the subject.

The most practical and important point developed by discussion is the time at which it is necessary to interfere. He did not think that a hemorrhage at the seventh or eighth month was prima facie evidence of placenta prævia. Such hemorrhage did not require us to make minute examination to ascertain the existence of placenta prævia.

In his own experience such hemorrhage has more than once occurred—owing, probably, to a partial separation of the placenta from the uterus—and still the patient has gone on to full term. He thought the safer rule was to regulate our conduct by the condition of the patient, rather than by a preconceived theory of placenta prævia. When the hemorrhage is repeated, or when it is sufficiently severe to threaten serious consequences to the mother, it is important to make an early and positive diagnosis. In the case reported, the oft-repeated hemorrhages, produced, as they were, without palpable manifest cause, strongly pointed to placenta prævia, but had there been only the first, or even the second hemorrhage, neither of which was sure, there would have been no adequate reason for making a thorough investigation; especially would there be no reason for resorting to the dilatation of the cervix spoken of by several of the gentlemen during this discussion. Extreme measures should only be employed when the health or life of the mother is threatened.

The very remarkable statistics reported by Drs. Miltenberger and Neale seemed to him fully to corroborate this view. If *Lomer* and his associates could accomplish the wonderful results achieved by them in cases operated upon "in extremis," and reduce the mortality to four or five per cent., then it certainly seemed entirely unnecessary to interfere at a very early period in an ordinary case.

Dr. G. L. Taneyhill was called to a case of another practitioner a few weeks previous to Dr. Williams' case. Hemorrhage was so profuse that the lady fainted. He diagnosed *placenta prævia*, and used ergot by the mouth and ice wrapped in flannel per vaginam, and *detained patient in bed.* At full term he was called in consultation. He prepared his hypodermic syringe with Bonjean's ergotine, gave one ounce of whisky, and expressed belief that the case would be a rapid one. During the consultation the waters broke, the attending physician, according to a previous understanding which they had, thrust in his right hand, grasped the feet, and *turned.* The head was easily delivered by drawing the child up over the abdomen; the placenta was immediately discharged. The womb contracted promptly by use of ice to abdomen. Did not use the ergotine. The child was dead, but the mother made a good recovery. Dr. Taneyhill had seen another case in which, by the administration of ergotine hypodermically, profuse hemorrhage was checked. The patient detained in bed to full term with good result to mother. He thought we could not guard too carefully a case of placenta prævia.

Dr. Neale said that all the means ever proposed for tamponing the vagina of a pregnant or parturient woman, he considered a bath-sponge the very worst. Pledgets of antiseptic cotton, *properly applied*, while the woman is in Sims' position and the perineum retracted, he believed to be generally considered the best. He did not suggest Braxton Hicks' method as applicable to all cases. Some required merely the rupture of the membranes, some the tampon, some Barnes' method, others forceps, internal podalic version, etc., etc.

Dr. Neale also said, he would be a bold man indeed, who would use a sponge-tent in the pregnant, parturient or puerperal conditions.

Dr. Miltenberger, in reply to a question by Dr. Wilson, said that Dr. Parrin's book, the latest out, says positively that there is not a single authentic case of death from chloroform during labor on record. The normal physiological hypertrophy of the heart with the effect of uterine contraction tended to prevent cerebral anæmia.

Dr. Williams had never seen any disagreeable effect from chloroform in mother or child.

Regular meeting, held February 8, 1887. First Vice-President, P. C. Williams, M. D., in the chair. Wm. E. Moseley, M. D., Secretary.

Dr. B. B. Browne reported a case of

Prolonged Gestation with Deformed Fœtus, Complicated with Amniotic Dropsy.

Mrs. K., aged thirty-six, married seven years, has had two children, both delivered with instruments. Menstruated for the last time March 20–23, 1886, expected to be confined about 28th of December, 1886, but labor did not come on until 2d February, 1887, being ten months from cessation of last menstruation. About October 15 she was kicked in the abdomen by one of the children and suffered for some time from the effects of this. On December 15 she fell down stairs, and was considerably stunned by the fall. At the time of birth of the fœtus there was a very excessive flow of amniotic fluid, deluging the bed and floor of the room.

The fœtus was small with large head, lower part of face and mouth very small, the right arm and leg were short and club-shaped. The placenta was adherent, and was removed with difficulty.

In reviewing the history of this case, it seems probable that the kick in the abdomen received in October caused an injury to the uterus, which resulted in a paralysis of the muscular structure of that organ; from this cause resulted the defective development of the fœtus and the large accumulation of amniotic fluid; the over-distention and loss of contractive power in the uterus would also appear to have been the cause of the prolonged gestation.

Tarnier's Basiotribe.

Dr. L. E. Neale exhibited Tarnier's Basiotribe, and referred to the *N. Y. Medical Abstract*, Jannary, 1885, containing a translation by Dr. Paul Bar, from *Le Progrés Medical*, December 20–27, 1884, for a full description of the instrument.

The same number of the *Abstract* contained a very interesting article by Alexander Russell Simpson, M. D., on the "History of Embryulcia," in which he describes the five different groups of instruments designed for the performance of the operation, viz:

1. Craniotomies.
2. Cephalotribes.
3. Cranioclasts.
4. Cephalotomes.
5. Basilysts.

The Basiotribe was considered the best instrument hitherto designed for craniotomy in each and every one of the three stages of the operations, viz:

1. Perforation.
2. Comminution.
3. Extraction.

Dr. Neale's experience with the basiotribe was thus far confined to his class demonstrations of the operation of craniotomy where he uses the dead human fœtus with the improved Budin and Pinard Manikin. Here he has always found the instrument to act most easily and thoroughly, even where other instruments, *ex. gr.* Braun's cranioclast (craniotractor) and trephine had signally failed.

With the cranioclast we rely upon the pelvic walls exerting such pressure upon the opened head while it is dragged through the pelvic canal as to collapse the cranial vault, the base of the skull remaining uncomminuted, and often causing serious difficulty in its extraction. This method of operating necessarily subjected the maternal soft parts to a more or less dangerous pressure, which, with the basiotribe was obviated by the thorough comminution of the skull, base and all. The instrument is made as simple and antiseptic as possible, and is an excellent combination of (1) perforator, (2) cranioclast, (3) cephalotribe; and the speaker thought it would fulfil all the requirements for the

easy and safe performance of the operation.

Other destructive instruments were shown for the sake of comparison.

Dr. Neale then exhibited Tarnier's last model of the axis-traction forceps. (3) Prof. Wm. T. Howard's modification of the axis-traction forceps, of which he spoke very highly from his experience. (4) Budin's and other douche tubes.

Dr. C. H. Riley, in washing out the cavity of the puerperal uterus generally used the female tip, metal or hard rubber, of the Davidson syringe, and had found it to answer the purpose very well indeed. It is the right size and long enough, can be easily bent, and a fresh one can always be readily procured. He had also found the block-tin catheters very useful for the same purpose.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, February 25, 1887.

The President, Dr. James B. Walker, in the chair.

The President introduced the subject of

Artificial Feeding of Infants.

The importance of the subject all will admit, and depends on—

1. The inability of the mother to afford nourishment.

2. The demands of the child for the materials for growth, repair, and heat production; and for *protection* from indigestion and the numerous disorders of malnutrition.

The prominent indications of non-agreement of any food are excessive colic, vomiting, diarrhœa. The results are seen in losses of flesh, strength, vivacity, and color; non-development of general body or of parts, as of teeth; retardation of infantile accomplishments, psychical or physical, or even loss of those which have existed. One or many of these conditions may exist, and call for attention on the part of the physician to the imperative needs of the little patient.

In choosing a diet there is no established *law* save that the food shall be easily digested, non-irritating, and suitable for nourishment and heat production. If the infant have been nursing its mother, the *quantity* may be alone at fault. In all such cases artificial food should be made to *supplement* and *not substitute* the natural supply. The amount of artificial food must vary with each case, from every alternate feeding to two or three feedings daily. Should the *quality* of the mother's milk be at fault, or should she be unable to nurse her child from other cause, a complete *substitute* must be furnished.

Here unquestionably the best, because furnishing the most rational substitute, is the wet-nurse. But rational though it be, it has objections which sometimes are insurmountable. Among these are the expense incurred, the difficulty of getting one whose milk is altogether satisfactory; or this agreeing, the unsatisfactoriness of the individual herself, who, reins in hand, may, if inclined, drive the family to distraction. Apart from this, many mothers object to having their little ones nurse at other breasts than their own, even when the substitute is cleanly in person, character, and habits, and much more so if doubt exists, as it often must, upon these scores. While not decrying wet-nurses, indeed while claiming that for some infants they are our only means of salvation, the lecturer claimed that in most instances they are not indispensable.

In choosing a substitute for human milk for healthy children, the lecturer does not approve of the so-called infants' foods, manufactured on a large scale, and kept on the druggist's shelves. These substances, many of which have much virtue, find a sphere in the management of the sick; but, as a rule, may be eschewed in arranging a food for the well.

For most babies, condensed milk answers best for the first three to six months of life. Here, again, a choice may be made. There are several varieties of this food, most of which are supplied in quantities to grocers and druggists and lie an indefinite time on the shelf or counter, during which time they are liable to deterioration. This is not a matter of theory, but has been proven in more than one instance by an attack of severe indigestion and diarrhœa on opening a new can. The brand most satisfactory in the lecturer's experience is Canfield's, which is manufactured in Philadelphia, and is for sale only at the manufacturer's office, where its freshness and purity are guaranteed. Or if the sweetness of the condensed milk be an objection in an individual case, the "evaporated cream," a partially condensed milk prepared by the same firm may be used, having it served fresh every day, or every alternate day. Unquestionably, condensed milk is preferable for the young infant to the fresh (?) milk furnished by the middleman in our large cities.

If a child taking condensed milk is constipated, a small quantity of Mellin's, Horlick's, or Nestle's food may be used in each bottle, and will usually be all-sufficient.

At least until a food has proven satisfactory, the infant should be weighed at the end of each week, and should gain from three or four ounces to a pound weekly. If severe colic, vomiting, or diarrhœa occur without cause, such as teething, exposure, etc., some change is indicated. This will usually be the case, where condensed milk is the diet, somewhere from the third to the eighth month. Tho addition of oatmeal to the food may be all that is needed. It should be thoroughly cooked for three hours, then strained through a cloth, producing a white, semi-translucent substance, about the consistency of starch, as used by the laundress. Of this from one to three tablespoonfuls may be added to each bottle, according to the age of the child and its powers of digestion. Lime-water is an important addition to the artificial food, and should be used continuously for the first ten or twelve months.

In most instances, fresh cow's milk will have to be substituted for the condensed milk when the latter disagrees, or this, if obtainable pure, may be used from the first. This should be diluted to suit the age and should have added sugar, lime-water, and from a teaspoonful to two tablespoonfuls of cream to each bottle, varying the amount to suit the condition of the bowels. After the third month, or even before, some of the oatmeal gruel, prepared as already directed may be added. In cities, all the water used in preparing the food should have been previously boiled. Sometimes an irritable state of the bowels, induced by one of many causes may be benefited by the substitution for a few hours of barley-water, arrowroot-water, or gum-arabic-water; and on resuming the milk food, one of the above waters may be used as the diluent instead of plain boiled water. Sometimes the use of peptonized milk diluted with barley-water; or the addition to the milk food of "peptogenic milk powder" of Fairchilds, Brother & Foster, may be required for a shorter or longer period.

In the artificial feeding of infants the plain nursing-bottle with pure rubber nipple is better than spoon-feeding, giving exercise to the masticatory apparatus and stimulating to more rapid functional development the salivary function.

The subject was discussed by the different members, and the experience of each one proved that cow's milk in some form was the best food for a child which must be artificially fed.

Dr. Anna McAllister spoke of some interesting experiments which had been tried at the N. Y. Infant Asylum under the supervision of Dr. J. Lewis Smith, where in several autopsies on artificially fed infants it was found that in those fed on *starchy* food the pancreas was very small, seemingly arrested in its development, while in those fed upon *condensed* milk the organ was normal in size.

Dr. Edward R. Stone gave a verbal report of a case of

Uræmic Convulsions in Nephritis following Scarlet Fever,

in a child six years of age, in which a hypodermic injection of gr. $\frac{1}{12}$ muriate of pilocarpine gave most satisfactory results. The child had been in convulsions all day, but they were speedily checked after the administration of the remedy, salivation and diaphoresis setting in almost immediately. "Basham's Mixture" was used afterwards, and the child made an uninterrupted recovery.

Mary Willits, M. D.,
1527 *Green St.* *Reporting Secretary.*

PHILADELPHIA COUNTY MEDICAL SOCIETY.

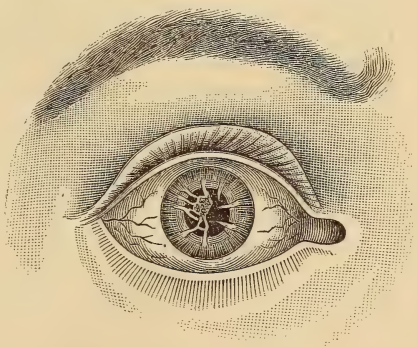
Stated meeting, February 23, 1887.

The President, J. Solis-Cohen, M. D., in the chair.

Dr. Charles S. Turnbull exhibited a patient presenting a

Persistent Pupillary Membrane.

I have brought before you to-night a case of unusual interest to opathalmologists and to medical men in general. The patient has



in his right eye what is known as a "persistent pupillary membrane." This is a remnant of fœtal life, but its exact structure has not been ascertained. Some consider it to be made up of atrophied blood-vessels, which have served their purpose. Other au-

thorities hold that it consists of the remains of connective tissue through which blood-vessels pass. In this man's right eye there is a network of hair-like fibres occupying the outer half of the pupil. These fibres originate from the anterior surface of the iris, and interfere in no way with the constrictor muscle of the pupil. This form of congenital anomaly was first observed about 1735, and on an average about one case has been reported every five years since that time. I am indebted to Dr. P. H. Bailhache; of the U. S. Marine Hospital Service, for the opportunity of exhibiting this patient.

The following discussion then took place:

Dr. E. Jackson said: "This case is notable for the clearness with which it shows the relation between the membrane and the iris. In all the cases I have seen heretofore, as in this, the pupillary membrane has seemed to arise from the anterior surface of the iris; but in no other instance has the connection been so obvious, the membrane here appearing to be simply an extension of the anterior layer of the iris, and similar to it in structure."

Dr. Turnbull said that the point referred to by Dr. Jackson is well illustrated in this case, and it settles the disputed question as regards the origin of these fibres. It is distinctly seen that the sphincter muscle is in no way involved. The membrane has no connection with the muscle nor with the inner pupillary margin.

The Treatment of Pneumonia in the Philadelphia Hospitals.

The following is from the *Med. News:*

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

Dr. Pepper reduces the initial high fever in cases of pneumonia in his wards (if, as unfortunately rarely happens, the case has been admitted just after the onset) by antipyrin or by the external use of cold water. It was for this, accompanied with severe pain, that venesection was formerly used; and he still advises its use at this earliest stage if high fever returns promptly after reduction by the above remedies. They will often produce a favorable impression, however, with less risk. Throughout the disease the fever must be carefully watched and often requires to be promptly reduced. Sometimes large doses of quinia—as thirty or forty grains given in two doses at intervals of four hours—will do this; but antipyrin or thallin or antifebrin is so much more prompt and certain that he prefers using one of them, and especially antipyrin, for the occasional control of hyperpyrexia, while giving continuously a moderate amount of quinia, say ten or twelve grains daily. Quinia meets several indications in pneumonia, and he nearly always gives it, adapting the dose to the grade of disease and special conditions of the patient. As the stomach must be very carefully guarded in pneumonia, and everything avoided that might irritate it, it is often better to give quinia by the rectum.

He is more in the habit of using aconite than veratrum, but one or the other of these powerful and reliable arterial sedatives should be used during the early days of the attack, given in frequent and moderate doses so as to produce safely their physiological effect by lowering the pulse-rate, relaxing the system and aiding in reduction of fever. Later, if the pulse loses force, or after the area of the disease has become defined, the indication for arterial sedatives has usually passed.

Not only must care be taken to avoid irritation of the stomach, but in many cases, especially in the early stage, there is much gastro-hepatic congestion and irritation present, and here it is important to limit ourselves to relieving this by short courses of small doses of calomel with or without soda, using meanwhile quinia by the rectum to control fever. It is especially in these cases that aconite is preferable to veratrum on account of its less tendency to irritate the stomach. After the disease is developed, ammonium carbonate is preferred to stimulate respiration and favor resolution. It is usually given in single emulsion and in doses of five grains every two or three hours for an adult.

The diet must be adapted carefully to the state of the stomach. It should be liquid throughout, and for the first two or three

days should be very restricted, but after that may be more free and concentrated if well received. It is extremely important that the patient be not allowed to make any exertion. Rigid rest must, indeed, be insisted upon, for pneumonia is one of the diseases in which sudden death is apt to occur from any improper effort, as even of rising to sit upon a commode by the bedside.

The indications for alcoholic stimulants are drawn from the state of the circulation and nervous system. Many cases do well without any stimulus from beginning to end; but on the other hand, the signs of cardiac failure or of failure of nervous force, call for alcohol, which may be required to be given freely. Of course, it is to be adapted, as to amount and mode of administration, to the state of the stomach. In general, a layer of cotton or wool batting stitched inside of the merino undershirt, over the outside of which a layer of oiled silk is placed, is preferable to poultices. The latter must be made skilfully to be pleasant; they must be changed frequently, and unless this changing is done with great care there are both fatigue and risk involved. Of course, the above remarks apply solely to croupous pneumonia.

Dr. Osler in hospital practice recognizes two groups of pneumonic patients—the alcoholic and the temperate. A majority of the former die in spite of all treatment; a majority of the latter get well with any, or with no, treatment. That the mortality from pneumonia in the large, general hospitals is uniformly above twenty-five per cent., is due to the fact that to them are admitted the debilitated paupers of the community with systems undermined by exposure and drink, and in no state to combat an acute disease. Alcoholics with renal inadequacy rarely survive pneumonia.

When the disease is limited, the fever moderate, and the pulse good, a dilute acid mixture is given with Dover's powder to allay the pain and the cough. Cotton wadding, or, if the patient prefer, light poultices are applied to the affected side. Blisters are never used.

As the disease can neither be cut short nor essentially modified by any remedies we at present possess, in severe cases we have to watch and meet the tendencies to death.

1. Heart-failure from engorgement of the right chambers, and the lesser circulation, indicated by cyanosis and urgent dyspnœa. Free venesection can alone meet this danger, and should be performed on the first signs of cyanosis, with failing heart. Good results have followed the removal of from eighteen to twenty-five ounces of blood. It is often left too late, and to be efficacious should be done early. It is not always successful. Two cases bled this session died.

2. The fever, against which quinine, antipyrin, and antifebrin are employed; but the action of antipyretics in pneumonia is more uncertain than in other acute fevers. Cold sponging and the cold pack are more effectual when the temperature becomes dangerously high.

3. The increasing debility, systemic as well as cardiac, demands stimulation and careful feeding. A majority of the fatal cases die of progressive heart-failure, against which alcohol is given freely. Digitalis is also employed, but the full tonic action of this medicine is rarely seen in the weak heart of fever. Camphor and strychnine are useful in this condition.

Of medicines, carbonate of ammonium is freely given. Opium is used to allay the early pain and to quiet the cough. Extensive bronchitis with liquid expectoration is a contra-indication. Arterial sedatives are not much employed, but when the cases are seen early, aconite is sometimes given. In the mild cases they are not often needed, while in the more severe ones they may be positively injurious. Expectorants are rarely called for, and when used the ammonia and nux vomica fulfil the indications. A milk diet is given, varied as occasion arises.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

Dr. Bartholow observes that the treatment of pneumonia (acute croupous pneumonia) must be adapted to the varying conditions of its several stages. The therapeutical stages may thus be—congestion, exudation, crisis or lysis, resolution. When the proper period for crisis or lysis passes without the occurrence of the phenomena indicating it, only two terminations can be expected—subacute or chronic pneumonia; death.

At the onset, when the chill occurs, he gives a full dose of quinine (fifteen to twenty grains) and morphine (half a grain). He does not claim that this may abort the disease, although he believes it does sometimes effect this, but that it certainly does limit the extent of the congestion then taking place. During the stage of congestion and commencing exudation he employs two remedies chiefly, aconite and opium. Of the former, two drops of the officinal tincture; and of the latter, ten drops of the deodorized tincture, are given every two or three hours; double these amounts being adminis-

tered at the first dose. When exudation has occurred, for the aconite ammonia is substituted. He prefers the carbonate dissolved in the liquor ammonii acetatis, ten grains to the ounce, of which a tablespoonful every three hours is given.

During the first and second stages, should there be wakefulness or delirium, or the temperature continued high (at 105° or 106° F.), Dr. Bartholow prescribes chloral in fifteen grain doses, three or four times in the twenty-four hours. Indeed, he has found that cases do better with than without chloral, and this, probably, because chloral has a solvent effect on fibrin and fibrinous exudation. As it, also, lessens body-heat, and quiets restlessness, which is only less exhausting than delirium, it becomes directly useful as a remedy for these important elements of the morbid complexus.

As the crisis occurs, or the lysis begins, somewhere from the fifth to the eleventh day, attempts at resolution that might otherwise prove abortive, may be changed into a well-defined crisis by the timely administration of quinine or alcohol in an efficient dose. The indication for the use of one or the other of these remedies consists in the appearance of some one of these critical phenomena, without the concurrent presence of the others. A copious sweat, an attack of diarrhœa, the sudden return of the chlorides to the urine, the appearance of herpes on the lips, etc., are, of course, the usual objective evidences of the crisis. In the more serious cases, one of these signs may appear, and yet the attempt at resolution fail. It is then that the vital forces need the aid of one or both of these remedies to accomplish the revolution in the pathological process; then quinine, if the dominating factor is elevated temperature; or alcohol, should the cardiac energy appear insufficient; or both, if these conditions are combined.

The persistent use of quinine or of alcohol, according to Dr. Bartholow, is not to be commended. Quinine increases the digestive weakness, and alcohol, in any considerable quantity, embarrasses the circulation and impairs the oxygenation of the blood. Nevertheless, alcohol has a distinctive place in the treatment of alcoholic pneumonia. The pulmonary inflammation is often masked by the delirium tremens which is excited by the sudden withdrawal of the accustomed stimulus, and the failure of the nutrition; and hence, under these circumstances, the alcoholic food must be freely supplied.

As regards counter-irritation, he is clear that only a mild irritation is proper; for whilst this, by a reflex action, stimulates the vaso-motor system, and thus lessens congestion, severe counter irritation, on the other hand, depresses the trophic system, and hinders, rather than promotes nutrition and repair. A succession of mustard plasters, each applied only long enough to redden the skin slightly, is the best form of counter-irritant. Stupes of turpentine are cumbrous, oppressive, and disagreeable, and blisters are unsuitable, unless applied long enough merely to act as a rubefacient. The counter-irritant or rubefacient cone now made for topical applications, is a very convenient, even elegant, preparation for this purpose.

Venesection continues to be a *vexata questio*. In the old antiphlogistic days, bleeding was so completely overdone, that any merit it has was overwhelmed in the general condemnation. There are, however, two conditions of the circulation in pneumonia, in which a timely blood-letting is of great value: at the outset in a vigorous subject, when congestion is increasing in depth and extent; and at the approach of the crisis, when the heart labors in consequence of over-fulness of the veins, and ischæmia of the arteries.

The necessity for close attention to the state of the nutritive functions is distinctly recognized. As the gastric juice in cases of pneumonia is deficient in the constituents required for the formation of peptones, Dr. Bartholow is careful to supply them with aliment.

THE PENNSYLVANIA HOSPITAL.

In the treatment of acute pneumonia, Dr. A. V. Meigs ordinarily pursues a certain plan, which is modified according to the needs of each particular case. The patient is confined rigidly to bed, and, if advanced in years, it is important even that the bed-pan and urinal be used. Food is administered at regular intervals, and if the case be one of severity it should be liquid, and is best given every two or four hours. In severe attacks milk and beef-tea are given alternately every two hours, three or four ounces at a time. Medicines are given on a plan corresponding with the system upon which nourishment is administered, and usually are taken a quarter of an hour after food; thus the longest possible period of undisturbed rest is afforded the patient. A careful attention to details certainly in the long run conduces much to the recovery of patients. No stimulant is given in mild cases, particularly in young persons, so long as they progress with seeming safety. In severe attacks the

patient is freely stimulated, from two to twelve ounces of whisky, or in rare instances even more, being given in twenty-four hours. It is best given in the milk. Ordinary medicinal treatment is the administration in pill form every four hours of digitalis, gr. $\frac{1}{3}$; opium, gr. $\frac{1}{8}$; and quinine, gr. j. In severe attacks this is suspended and ammonia substituted, or the two are given in conjunction. The most reliable form of ammonia is the carbonate, of which five grains are given every two to four hours, according to circumstances, or there may be administered at the same interval a drachm of the aromatic spirit, or half an ounce of the solution of the acetate.

As yet it has not been his fortune to meet with a case in which he has thought it advisable to bleed, although he believes it to be good practice, if done judiciously in the early stage.

The application of dry cups is a measure often attended with great relief of the suffering, and benefit to the patient, in the early stage of the disease, particularly if the attack is complicated, as is very commonly the case, with much pleuritic pain. From eight to twenty cups are usually applied.

With regard to external applications, he uses no poultices, which are difficult to keep in place, and once begun are hard to get rid of, and become exceedingly troublesome when the sweating stage comes on. Sometimes he has cotton or wool, preferably the latter, sewed upon the inner surface of the shirt.

This is not the place to dilate upon the utter inadequacy of any known treatment to avert the fatal result in some of the more sudden and violent forms of the disease. A careful and patient pursuance of the plan detailed has proved more satisfactory in Dr. Meigs's hands than any other in the management of such cases as have been in his charge in the Pennsylvania Hospital, if they seemed amenable to any treatment.

PHILADELPHIA HOSPITAL.

Dr. Tyson recognizes that in the class of patients admitted to this hospital the sthenic form of pneumonia requiring vigorous antiphlogistic measures is rarely seen. He rarely, therefore, practices general bloodletting, but wet-cupping over the affected lung is frequently resorted to. The cupping is followed by jacket-poultices, which are continued until the case terminates favorably or unfavorably. Blistering over a liberal area is sometimes substituted for the cupping.

The antipyretic measures used are either digitalis and quinine in full doses, or quinine and the fluid extract of veratria, the latter in five-drop doses every two hour, until the pulse is decidedly reduced. Digitalis is used in cases where debility is conspicuous, and requires to be combatted. It is given in doses of fifteen drops of tincture or two fluiddrachms of the infusion every three hours.

From the onset, stimulants are freely used, and half-ounce doses of whisky are given every two hours, or hourly; while it is not unusual to give an ounce of whisky every hour. It is generally given in the form of milk punches.

Stimulant expectorants are given only when the exudate begins to soften, as indicated by the *crepitans redux*, and cough tending to become loose. Carbonate of ammonium is generally used in doses of from five to ten grains. In cases requiring less stimulation, the ammonium chloride is prescribed in fifteen-grain doses. An old practice of the hospital was to give the officinal liquor potassæ as an expectorant, with the idea that it "thinned" the viscid secretions. There is reason to believe that potassium carbonate has a similar effect.

Dr. J. C. Wilson treats his cases of lobar pneumonia in the wards of this hospital symptomatically. The patients, who are drawn from the pauper class or those closely bordering upon it, are not often young, almost always debilitated by destitution or previous disease, frequently the subjects of chronic alcoholism. A considerable proportion of them are admitted at the close of a more or less prolonged debauch. Very few cases of primary pneumonia develop in the wards. The patients are commonly received in the first week of the disease, but very rarely so early as the first day. Neither general nor local blood-letting is practiced. The plan usually pursued is as follows:

The patient is bathed and put to bed. If there be no reason to depart from the rule, a mild mercurial purge is at once administered. In case of diarrhœa, great exhaustion, or at an advanced period of the disease, it is omitted. A small dose of opium or a hypodermatic injection of morphine follows after a time, and is repeated occasionally during the attack, as may be required to control pain or induce quietude and sleep. After the bowels have been relieved a single large dose of quinine, rarely less than xvj or more than xx grains, is given. From this time until defervescence quinine is not again used except in response to some well-defined indi-

cation such as excessive pyrexia. Ammonium carbonate in v grain, less frequently vijss, or x grain doses, is given every second hour, in many cases, throughout the attack. Alcohol is freely used, the frequency and amount of the dose being regulated by its effect upon the heart and nervous system, the total quantity in twenty-four hours seldom exceeding twelve fluid ounces of whisky. In favorable cases with moderate fever, and especially in the absence of a previous history of addiction to drink, it is used sparingly. Nevertheless all the cases receive a certain amount of alcohol. Pyrexia, when moderate, demands no special therapeutic measures; when intense, it is treated by ice-poultices to the chest, cold compresses, the cold pack, antipyrin, or large doses of quinine. Digitalis, veratrum, belladonna, and aconite are very seldom used, and then only to fulfil special therapeutic indications. Pilocarpine is not regarded as curative. The diet is light, bland, nutritious, and of moderate amount. Turpentine stupes are repeatedly applied, sinapisms occasionally, blisters never, save in cases of delayed resolution. Poultices are only exceptionally employed, a light jacket lined with cotton batting or fine carded wool being found more comfortable, more convenient, and fully as useful.

Upon the occurrence of defervescence alcohol is rapidly decreased in amount, the diet increased, solid food added, and quinine in smaller doses administered. It is usually advantageous to give iron or arsenic for a time. Flying blisters, or the external use of iodine and small doses of potassium iodide, may be useful in delayed resolution. Convalescent patients are not kept long in bed, but are encouraged to sit up and move about as soon after complete defervescence as their strength will permit.

Despite the greatest care in the management of this disease in the Philadelphia Hospital, the death-rate, owing to the character of the patients, is high.

Treatment of Paralysis from Compression of the Spinal Cord Caused by Fracture of the Spine.

In the *Centralblatt für Chirurgie*, No. 51, 1886, Dr. Carl Lauenstein, of Hamburg, reports a case of progressive paralysis from fracture of the spine, which was treated with much success by the resection of two vertebral arches at the most prominent part of a posterior angular projection in the dorso-lumbar part of the column, and by the removal of pressure from the corresponding part of the cord. The patient, a Norwegian seaman, 18 years of age, came under the author's care five weeks after he had received a severe injury to the back through a fall from a height of about forty feet. This accident had been followed by loss of power in the lower limbs and incontinence both of fæces and urine. In the dorso-lumbar region was a marked angular projection of this portion of the spinal column, the most prominent part of angle being just over the spine of the last dorsal vertebra. The patient was unable to stand, and when in bed could raise each leg and perform slight movements, both of flexion and extension in each of the joints of the lower limbs, which were much emaciated. There was no impairment of sensibility. The surfaces of the paralyzed limbs were cold, and the right foot presented some œdema. The urine was purulent and alkaline. An attempt was first made to relieve the spinal cord of compression by extending the distorted column and by applying a plaster jacket whilst the patient was suspended. This treatment has no good result: the cystitis became more intense, and after three weeks loss of sensibility could be be made out in front of the right thigh over the region supplied by the ilio-inguinal and crural nerves. Dr. Lauenstein then decided to make an atempt to remove the pressure by direct surgical operation performed with antiseptic precautions. On March 6, the patient having been narcotized, a vestical incision was first made from the spinous process of the tenth dorsal to that of the second lumbar vertebra, The soft parts, including periosteum, having been dissected back on either side, the arch of the last dorsal vertebra was removed in several fragments by means of a chisel. The lumbar portion of the cord and the cauda were found to be lying close under the bone, to which the dura mater was so adherent that a portion of this membrane had to be removed. As the cord was found to be still compressed below the gap thus formed, the arch of the first lumbar vertebra was removed by the chisel in one piece. The wound was then drained at its inferior angle, and its edges fixed together by catgut sutures. The wound healed speedily by first intention, and the general condition of the patient was not impaired in consequence of the operation. On the eighth day after the operation the urine had become slightly acid, and the anæsthetic region on the surface of the right thigh had diminished in extent. Two months later the patient could empty his bladder, and had regained much power over his lower limbs.

At the end of May he was able to stand, and after another month could walk with the support of a stick. In August the patient, whose appearance and general condition had much improved, was able to walk about during most of the day without any support. There was no longer any sign of incontinence of fæces, the urine could be retained for as long a period as four hours, and there was seldom any call to relieve the bladder at night. Early in September the patient was able to travel to his home, in Norway. With the view of deciding the question whether such improvement as had resulted in this case could possibly have been attained without the performance of a surgical operation, Dr. Lauenstein has looked over published reports of similar cases, and studied especially the statements referring to paralysis of the bladder. The relief of this condition, he states, is a point of much importance, for, with the exception of bed-sore, which usually occurs in such cases, cystitis is undoubtedly the most formidable of all the secondary symptoms. Of fifty-three cases of so-called cure of fracture of the spine, collected by Gurlt in his work on fractures, there are fifteen instances of spontaneous restoration of the functions of the bladder and rectum. The shortest interval between the date of the accident and that of complete restoration of the functions of these organs was a few hours, and the longest interval eight weeks. In not one of six cases of fracture of the spine with paralysis of the bladder, treated by Lauenstein during the last six years, was any spontaneous improvement observed in this latter condition after long intervals.

It is concluded from those returns that when, in cases of compression of the cord from fracture of the spine, the functions of the bladder and rectum are restored, this restoration usually takes place after a brief interval, and that if no improvement has taken place in the course of ten weeks, any subsequent spontaneous change for the better in the condition of the bladder can hardly be anticipated. In the case reported by Dr. Lauenstein the bladder symptoms just before the operation were rapidly increasing in severity. Since the introduction of the antiseptic method into practical surgery two instances have been reported of operative interference for the relief of paralysis from injury to the spine. The first of these, reported by Maydl, from the hospital practice of Albert, had been diagnosed as a case of fracture of the spine in the dorsal region, but was found to be one of luxation and crushing of the cord. The patient recovered from the operation. In the second case, reported by Lücke, the operation was performed two days after an injury to the spine, which was found to consist in fracture with crushing of the corresponding part of the cord. This patient also recovered from the operation, but died nine months later from marasmus, and without any but very slight improvement having been observed in the condition of the paralyzed limbs. In six only of thirty-one cases collected by Werner of operations performed on fractured spine in the pre-antiseptic era did the patients recover from the effects of the operation. These results, however, Dr. Lauenstein holds, cannot be brought forward to discredit the operation of trephining the spine, since sufficient care was not taken in their selection; and the treatment was applied in instances both of recent and of old injury, and even of complete crushing of the cord. Dr. Lauenstein would not operate in a case of recent injury to the spine, as it is well known that occasionally in such instances the symptoms of paralysis disappear spontaneously in the course of a few weeks.

Indications for Using Hydrochloric Acid in Gastric Diseases.

The following is the substance of an article contributed to the *Deutsche Med. Wochensch.*, No. 35, 1886, by Professor Franz Riegel:

Until very recently it was commonly thought that in most cases of chronic dyspepsia the secretion of juices by the stomach was diminished. Accordingly, hydrochloric acid was nearly always prescribed, either with or without pepsine, without its being in each case proved that there was actually a diminution of secretion. The result was that only in a few cases did rapid improvement take place, while in most cases there was no result from the use of the acid, and under certain conditions there followed even exacerbation of the dyspeptic symptoms. The explanation is easy. The fact is that, instead of the secretion (particularly of hydrochloric acid) being reduced in the majority of cases of chronic dyspepsia, there is, on the contrary, in a considerable number of cases, actual increase of such secretion.

The clinical appearance of hyper-secretion in the more pronounced and chronic cases is so marked that the anamnesis already points to the diagnosis. The latter is more difficult in less pronounced cases when there is hyper-secretion and hyper-acidity. Here a

chemical examination as to quantity and quality is necessary to determine accurately the nature of the disturbance of secretion.

Riegel does not consider it justifiable to follow Leube's plan of prescribing, in most cases of chronic dyspepsia, a trial dose of hydrochloric acid and pepsine. He recommends the use of Congo paper, first introduced into the diagnosis of gastric diseases by R. von Hösslin. This paper can easily discover 0.0019 per cent. of free acid, it being only necessary to put a drop of the contents of the stomach on the paper. If there be acid the paper turns blue, and the more acid the deeper the blue; while if there be very little or no acid the paper keeps its red color. This method alone cannot decide whether the free acid is hydrochloric or lactic, but if there be a very perceptible reaction the presence of hydrochloric acid may be assumed, since, even when greatly diluted, it produces a deep blue color, while lactic acid, in a concentration of under one per cent., causes a far less intense change of color.

To test the efficiency of the Congo paper Riegel examined upwards of one thousand pecimens of gastric juice with it, in every case making at the same time an artificial digestion, the quantity of the acid being compared with the Congo reaction. In every case in which the juice clearly colored the paper, the filtered fluid digested albumen well, thus bearing out Riegel's opinion that there is scarcely ever a lack of pepsine when there is a sufficient quantity of hydrochloric acid. The intense blue of the paper often pointed to hyper-acidity.

The use of the Congo paper does not do away with the necessity of other reagents, the digestive tests, and the determining of the quantity of acid, for scientific purposes. But in a doctor's practice these latter are not practicable; thus it is that Riegel recommends the use of Congo paper, (1) as a *diagnostic* criterion to determine whether there is sufficient hydrochloric acid or not, and (2) particularly as a *therapeutic* criterion to ascertain whether hydrochloric acid should be prescribed. Only when the Congo paper remains red, or becomes but very slightly blue, is hydrochloric acid to be ordered, but then in much larger doses than are generally given; never to be taken directly after a meal, but at least an hour or an hour and a half after. In cases of hyper-acidity, when the paper becomes intensely blue, instead of using hydrochloric acid, prescribe rather neutralizing remedies, such as bicarbonate of soda, etc.

The following example is given. The patient takes a mixed test-meal. In about six hours, or earlier it may be, no other food or drink having been taken in the meanwhile, some of the contents of the stomach must be drawn, a soft Nélaton probe having been swallowed by the patient, which is easily done with a little help from the doctor. No water must be added. The microscopic appearance of the contents of the stomach may alone lead to important conclusions as to the nature of the disturbance of secretion.

Then a drop is put on Congo paper, or a strip of the paper is dipped in. If the paper turns blue, there is hydrochloric acid, and *vice versa*. Riegel repeats that in recommending this procedure, he has not in view exact scientific results, but practical help to avoid the too generally indiscriminate use of hydrochloric acid.

Pepsin Injections in Tumors.

Dr. W. H. Morse, in the *Med. Register*, reports his use of pepsin (Jensen's crystal) in the local treatment of tumors. He used one part of the pepsin to three of distilled water. He writes:

"My results have 'almost always' been uniform, and in referring to the exceptional cases do not understand me as having occasion to find fault with the pepsin. The sole reasons for failure have been due to extraneous causes, or when the neighboring lymphatics were involved. Thus in the main, my results have tallied with those of Thiersch, Nussbaum, and Broadbent, and this, both as regards benign and malignant tumors, some of them unmistakably cancerous.

"Reports of cases are, at the best, dull reading, and moreover are more dull to write, therefore, I will not burden the busy reader with the details of my note-books. Yet, as to the matter of proof, I will submit something in the way of items.

"1. Recurrent carcinoma, as large as a hen's egg, seated in the right side of the inferior maxilla; suppuration excited by injection, and the tumor diminished to size of a hazelnut.

"2. Another carcinoma of same size, situated in the right breast of a woman; suppurated after seven injections; and in the course of a month the residuary nodule was scarcely as large as a marrowfat pea.

"3. A primary carcinoma of the size of a turkey's egg, situated back of the ear of a young man, was treated in the same way to one injection every twelve hours; after

twenty-one injections, suppuration took place; ultimately an entire disappearance of the tumor.

"4. Subcutaneous nævus, angle left eye; child; size of filbert; suppuration avoided only by occasional injections; after four months, reduction complete, save the clot.

"5. Interstitial fibroid of uterus; needle introduced through the vagina; anæsthetic employed; after several injections all accompanying symptoms removed, and the cure was considered complete."

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. Charles W. Allen, of New York, has published some observations on the supposed micro-organism peculiar to gonorrhœa, the "gonococcus," and Prof. Roux's method of confirming its identity. He maintains the existence of such a specific microbe, but acknowledges that its discovery has not aided us in treating the disease.

——A method of shortening the round ligaments of the uterus by means of Alexander's operation, is described in a reprint by Dr. Thomas A. Ashby, of Baltimore, Md.

——Dr. Andrew F. Currier, of New York, in an article lately reprinted, describes the palliative treatment of cancer of the uterus, and offers several valuable suggestions. His article was read before the Medical Society of the State of New York.

——The Messrs. Lilly & Co., of Indianapolis, have issued a small volume of 188 pages, entitled a "Hand-book of Pharmacy and Therapeutics (Lilly)," in which they present to the profession their numerous pharmaceutical preparations.

——Dr. E. C. Morgan, of Washington, D. C., sends us reprints of his two papers: "The Question of Hemorrhage following Uvulotomy," and "The Bursa Pharyngea and its Relation to Naso-Pharyngeal Disease." They are both papers which should attract the attention especially of laryngologists. The dangers of uvulotomy are well exposed.

BOOK NOTICES.

Sphygmography and Cardiography, Physiological and Clinical. By Alonzo T. Keyt, M. D. Edited by Asa B. Isham, M. D., and M. H. Keyt, M. D. Cloth, 8vo. New York: G. P. Putnam's Sons, 1887.

The late Dr. A. T. Keyt, of Cincinnati, devoted himself with untiring zeal to his professional duties, and to the development of the graphic system applied to the circulation. His results were published in various journals, etc., and are now collected into this volume by the editors. They are classified under a physiological and a clinical section. The former treats of such questions as the velocity of the pulse wave, an inquiry into the causes of the variation of this velocity, and on the mechanism of the cardiac and arterial traces. The influence of muscular exercise on the pulsations, and the forms of the pulsations of the fontanelle, are other interesting topics discussed.

Under the clinical section there is a very thorough discussion of the sphygmographic results in aortic, mitral, and tricuspid diseases, and a special study of the "presphygmic interval" in disease. The pages of the work are illustrated by numerous tracings and other cuts. It is a singular commentary on Dr. Keyt's profound studies of cardiac disease that his own death occurred suddenly and unexpectedly from cardiac degeneration, which he does not seem to have suspected.

Manual of Treatment. A Concise Presentation of the Modern Methods of Treating Disease. By C. F. Taylor, M. D., and W. F. Waugh, M. D. 1 vol., 8vo., cloth, pp. 532. Price $4.00. Published by the *Medical World*, Philadelphia.

The plan of this work may be briefly stated as follows: All diseases, from first to last, are arranged generally under their popular names, in alphabetic order; the treatment of each as found in the books is stated seriatim, beginning with that the authors deem most generally used. References are given to authorities by names but not by writings. All diseases are included, medical, surgical, of children, and of women. Precise formulas are quoted in a number of instances, but there is not much attempt on the part of the authors to exercise a critical judgment upon the very diverse methods of treatment suggested. There is a degree of utility in books of this kind when properly used, which some in the profession have not been inclined to recognize. They enable the physician to see at a glance what the suggestions toward treatment have been by a number of leading practitioners, and this is a good deal for him to gain.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

A PERSONAL STATEMENT BY THE SENIOR EDITOR.

It is unpleasant to make one's personal affairs the theme of public discussion; but when several newspapers choose to insert statements conveying erroneous and injurious representations, an equally public defense must be made. For this reason the senior editor of this journal, Dr. D. G. Brinton, who has also been its publisher for more than fifteen years, feels obliged to take notice of some recent articles in non-medical periodicals:

The first appeared in *The Evening Bulletin* of this city. Referring to a litigation which for about a year has been pending between Dr. Brinton and the heirs of the late Dr. S. W. Butler, it says: "Dr. Brinton has withheld all payments made under a lease which was entered into on May 25, 1886, and dated May 1."

This statement is a gratuitous and malicious falsehood, not containing a vestige of truth. So far from withholding payments, as stated in the *Bulletin*, Dr. Brinton paid them regularly, and can produce the receipts for them, up to the month of October, 1886; and subsequent to that date tendered the money himself to the attorneys of the Butler heirs in this city, and, by an agent, to those heirs themselves, who were residing out of the State at Asbury Park, N. J. In both instances the tender was refused, and since that time the Butler heirs have never asked Dr. Brinton either personally or under their hands for the amount due them, nor singnified to Dr. Brinton their willingness to accept it. This has probably been under the advice of counsel, and may be good, legal policy, but for the *Bulletin* to publish the contrary was either gross ignorance or the inspiration of unscrupulous malice.

The falsehood was copied by a paper called *The Shore Press*, issued at Asbury Park, New Jersey, with an editorial comment as follows:

"In addition to the above, we understand that although a statement of the receipts and expenses of the business for the last seven months of the old contract was due the Butlers at the time the present agreement went into effect on the first of May last, it has never been furnished."

This is as equally unwarrantable a falsehood as the former. A statement of the balance due Dr. Brinton by the Butlers was filed in the courts of this city in September last, and as the Butlers did not reside in the State, what is known as a *foreign attachment* was obtained, by which the property of

persons who do not live in the State can be held as security until they choose to offer some other acceptable security, or show that they do not owe the debt. Both these courses have been open to the Butler heirs; the accounts *The Shore Press* refers to have been ready for their inspection at any time; but they have never asked for them, never called the case for trial, and never offered other satisfactory security.

Dr. Brinton, on the other hand, proposed to them through their attorneys and directly through a member of their family, either to refer this dissension to arbitrators, to call it up in court and have it adjudicated, or to settle it in any other way which would be prompt and protect the rightful interests of both sides. His overtures have been refused. Furthermore, although the attachment justified him in refusing to pay the monthly amounts due the Butler heirs under the contract of May 1, 1886, yet fearing that the non-receipt of this sum might incommode them, and desiring that the litigation should proceed as amicably as possible, Dr. Brinton, as above stated, tendered the full monthly sum as usual, and was met by a flat refusal both by them and their attorneys.

The editorial comments of the *Bulletin* and *Shore Press* were in issues of those journals in January last; but the senior editor of this journal considered that such mean falsehoods were best answered by silence. Within the last month, however, he has found that copies of the *Shore Press* have been sent to professional and business men in this city quite recently, and with these atrocious articles marked. They may also have been largely distributed elsewhere, and it is to meet and refute these calumnies to the subscribers to this journal and to the press at large which is his apology for thus bringing a portion of his private business before the public.

DR. BOWDITCH ON IRREGULAR CONSULTATIONS.

Dr. Henry J. Bowditch, formerly Professor of Clinical Medicine in the Harvard Medical School, and for one year President of the American Medical Association, took a lamentably poor position for himself last June, when he delivered an address before the Rhode Island State Medical Society in which he advocated the fraternization of the regular profession with eclectics, botanics, homœopaths, and every other ism or pathy which can get legal recognition anywhere.

The address has now been published by Cupples, Upham & Co., Boston, and is a sad commentary on Dr. Bowditch's present state of mind. He urges (p. 18) that every regular physician shall be allowed by the regular code to consult with eclectics, homœopaths, etc.; he wishes these unscientific practitioners admitted to state medical societies and the American Medical Association on an equal footing; and he opposes the respect for the Code of Ethics inculcated by the American Medical Association.

Yet with strange and gross inconsistency, Dr. Bowditch is particular to state that he himself would never touch the meat he thus offers others to eat. Referring to his own actions toward irregular practitioners, he says:

"Before closing let me say in a few words what course I have pursued in regard to consultation with homœopaths and eclectics. I have never voluntarily consulted with members of either of these sects. It is true that on one or two occasions I have been unwittingly brought into contact with them. When asked to consult with a homœopath, I have replied, 'It would be useless for us to meet, because I have no faith in his system, and if he does not believe in it *while claiming to be a homœopathist*, he acts wrongly, and for that reason I do not wish to meet him in consultation.' If the appellant should urge me to visit the patient without the knowledge of the attending homœopathist or eclectic, I have always declined doing so."

In other words, while Dr. Bowditch gives an unanswerable reason on one page why no honest regular practitioner can consult with one claiming to be distinctively an eclectic, homœopath, etc., on the next page he insists that this liberty to violate the professional sense of duty should be extended to all, without challenge! Who is prepared to be led by an adviser who juggles in this way with the plain dictates of conscience? We are sincerely pained to witness Dr. Bowditch, toward the close of his long and honorable career, thus blind himself and seek to blind others to the moral aspects of this important question.

ON THE TREATMENT OF MALIGNANT TUMORS WITH ARSENIC.

That the treatment of malignant tumors, which for some reason or other cannot be extirpated with the knife, by arsenic, has led again and again to a radical cure, may be noticed from the last report of the surgical clinic in Tübingen (*Deutsche Med. Zeit.*, February 21, 1887, p. 173). Altogether 59 cases were thus treated, the male sex being represented by double the number of the

female. The treatment consisted in the administration of a mixture of Fowler's solution and tinctura amara, or tinct. ferr. pomat., āā. Of this mixture five drops were given three times daily, and every second or third day—according to the urgency of the case, and the more or less rapid extension of the disease—this dose was increased by one drop, until finally the dose amounted to 40 and 45 drops, when the doses were slowly diminished in the same manner as they had been gradually augmented. Whenever mild symptoms of beginning intoxication made their appearance, the remedy was omitted for a few days.

Occasionally instead of the internal administration, the arsenic was used hypodermically, the injection being made directly into the parenchyma of the tumor or, more seldom, into the neighboring parts. Fowler's solution and aq. dest. āā was the mixture employed. A Pravaz's syringe usually is subdivided into small spaces by lines each indicating from one to five drops. At the beginning one such subdivision was filled with the mixture and injected, and this quantity was gradually increased until from 4–5 spacesful were employed each time for the injection. To determine whether the treatment with arsenic in the case of malignant tumors will be successful or not, it has to be continued at least for two months. A com plete cure was obtained in seventeen (of the fifty-nine) cases. The period of treatment varied in the cases cured from one to six months. Though the number of successful cases may appear small, it is large enough to encourage us to try the treatment in every case, especially as all those in whom it was employed were such of general sarcomatose, or where the malignant symptoms indicated an infection of the blood and an early fatal issue.

Notes and Comments.

An Interesting Case of Chorea.

Drs. E. Ziegler and C. Nauwerk have published a work on Morbid Anatomy, in Jena. In it we find the following case of chorea reported, which derives special interest from the fact that death ensued, and that a careful microscopical examination of the whole central nervous system demonstrated the cause of the disease.

A girl, æt. 7, for some weeks prior to the outbreak of the neurosis had been complaining of general lassitude. She seemed to become easily very tired, and at the same time greatly lost in bodily weight, so that by the time the first symptoms of the real malady made their appearance, she had become greatly emaciated. Within two days the chorea spread over the whole body, and six days later death ensued.

The autopsy revealed an inflammatory condition mostly developed in the upper part of the medulla oblongata, also in the pons and in the crura. In the internal capsule small foci of inflammation were met with. The next most striking appearance was the presence of innumerable punctiform hemorrhages. They were specially frequent in the crura cerebri, the inner capsule, and in the inflamed portions of the pons and the medulla. Capillary embolism was not found, but the extravasations were rich in leucocytes. The nerve-fibres gave evidence of degeneration. The disease seemed therefore to be due to an inflammation of parts of the central nervous system, accompanied by capillary hemorrhages, and as the morbid picture greatly resembles that met with in some cases of acute infectious disease, there is a probability that the choreic symptoms were due to some infectious material which selected as its seat those portions of the brain where the inhibitroy centre for motion resides, thus removing the motor impulses from the direction of the will.

We think that later investigations will establish the fact that chorea is an infectious disease, caused by micro-organisms, which give rise to embolism mainly in the fine arteries leading through the anterior perforated spaces to the corpora striata, while in very acute and virulent cases they produce hemorrhages, which in their turn cause a fatal and widespread inflammation. Such a theory, at least, would explain many of the phenomena of the choreic disease.

Physiological Action of Cocaine.

Dr. Freiberg, working under Dr. Blumenthal, at Kowno, Russia, has arrived at the following conclusions respecting the physiological action of cocaine (*Berl. Klin. Woch.*, No. 10). Cocaine is a powerful anæsthetic, its action being limited to the surface in its immediate neighborhood; and when brought into contact with an exposed nerve the anæsthesia is distributed over the periphery, but the central end of the nerve and motility are unaffected. In doses of half a grain to a grain in rabbits, and rather more in dogs, cocaine causes anæsthesia of the cornea, dilatation of pupils, retraction of eyelids, and exophthalmos; tonic and clonic spasms may

occur, with loss of consciousness, and often fatal issue. The epileptiform spasms are doubtless of cortical origin. A difference as to the anæsthesia is observed between dogs and rabbits when cocaine is applied to nerve-trunks. In dogs reflexes are abolished; in rabbits they are increased. Cocaine has a special affinity for the sensory and terminal sensory fibres of the cortex cerebri, whose function it inhibits. The disturbance of co-ordination may be attributed to interrupted conduction in the sensory fibres, both central and peripheral; and the convulsions, which are the main cause of death in cocaine poisoning, are due to the vaso-motor spasm and anæmia of the cortex. Bromide of potassium and the application of cold to the surface counteract this tendency; but with the first appearance of symptoms of cerebral anæmia, these toxic effects of cocaine may be mitigated or banished by nitrite of amyl.

Adenoid Growth in the Nose.

There are various kinds of adenoid neoplasms that may be met with in the nose. It has been the general opinion of surgeons that to prevent their recurrence a total extirpation should be aimed at. Dr. Lowenberg (*Deutsch. Med. Wochenschr.*, 6, '87,) has invented a new instrument for the removal of these bodies. It consists of a knife which, while being proctected by a shield all around it, has a cutting edge only on one place, where in the protector an opening is left, which, at the time of the introduction of the instrument, is guarded by a movable slide. The latter, on being withdrawn, exposes the keen cutting edge, and the apparatus thus enables the operator to make a strictly local application. According to L. the adenoid growths can be removed much easier with his knife than with any other instrument. One observation of his is rather peculiar, viz., that one should not endeavor to remove every and all trace of the neoplasms, but that it suffices simply to make room enough for the air to pass through uninjured and to lay the ostia of the tubes free, as the remainder of the vegetations is innocuous, and gradually atrophies of its own accord after the larger part of it has been destroyed by an operation. Dr. Lublinski, who had great experience in these cases, found that most of these vegetations cease in later life, they slowly diminishing away.

Motor-Cortical Centres.

Dr. Paneth has repeated to some extent the experiments made on animals first by Schiff and Ferries (*Prag. Med. Ztsch. f. Alk.*, 1886, vii., p. 75). By the aid of the galvanic current he irritated the various zones of the motor region in dogs, his especial aim being as strictly as possible to keep within the boundaries of each cortical area so as to succeed in obtaining contractions of individual muscles wherever their motor impulse originates. In this way he investigated a number of cortical centres for single muscles of the fore and hind paw, and for the facial centre he selected the excitable zone for the orbicularis palpebrarum. Afterwards he isolated the centre by cutting off all surrounding cortical portions and severing, also, all parts beneath, and he then investigated the success of galvanic irritation. The results which he obtained are the following:

From one part of the cerebral cortex, the posterior segment of the sigmoid gyrus, fibres pass promiscuously to the muscles of the extremities and of the trunk; from another part of the cortex, outside of the first region, fibres pass to the orbicularis palpebrarum, and to the other muscles provided with motion by the facial nerve. All these fibres pass directly from the motor region to the individual parts of the body. The zones, however, from which they start for the muscles of the extremities are not isolated nor do they lie near each other; they are neither punctiform nor sharply bounded, but are mixed up with each other.

The Etiology of Dysentery.

In a communication to the Bohemian Medical Society Prof. Hlava gives an account of a number of observations he has made on the subject of the etiology of dysentery. He examined the stools and the bowels with their contents post mortem in sixty cases of epidemic dysentery, also in two cases of a sporadic nature, and in ten where the symptoms of dysentery were developed as complications of other diseases. He also injected the fresh stools of dysenteric patients into the rectum or duodenum in seventeen dogs, six cats, eight rabbits, hens, and porpoises, and made seventy cultivations of bacteria of various kinds found in dysenteric stools. The conclusion he arrived at was that bacteria are not the cause of dysentery, for none of the micro-organisms were reproduced in the animals experimented upon, only a transitory catarrh being found. No qualitative anatomical distinction could be made out between cases of epidemic and of sporadic origin. Prof. Hlava investigated the amœbiform large-grained protoplasm which he

found in the dejections in considerable quantity in sixty-five cases, and on the intestinal mucous membrane and in the submucous tissue in twenty cases. On putting these bodies under the microscope, he found that the amœboid movements continued for ten hours. He has commenced a series of observations on the effects of injecting them into the intestines of animals, with the object of showing that these bodies have a causal relation to the disease.

Incontinence of Urine in the Female.

After an operation for stone, consisting in crushing the stone after sufficient dilatation of the urethra in a woman, large pieces of the stone were pulled out through the urethra by Dr. F. Winkal (*Centrlb. f. d. Med. Wiss.*, February 2, 1887). The consequence was incontinence of urine, but on inquiry W. found that the patient had previously been suffering at certain times from the same complaint. He then made a series of operations, with the result of achieving a cure. First. W. received a piece 1 ctm. wide and 8 ctm. long out of the anterior vaginal wall. Immediately after an improvement set in, which was, however, but temporary. Next W. executed resection of the anterior portion of the urethral wall. This was followed for two years by a cessation of all incontinence. Then the symptom returned, and an examination showed that the urethral orifice was too much dilated. To remedy this defect, W. cut out a wedge-shaped piece, and then sewed the parts together. This operation, too, brought about improvement, but no cure. Renewed examination demonstrated the presence of a thin part of the urethra near the neck of the bladder. W. resected this portion by removing the vaginal wall and the muscularis of the bladder without injuring the vesical mucous membrane. This fourth operation at last established a permanent cure.

Treatment of Diphtheria with Hydrogenium Superoxydatum.

Former experiments have amply demonstrated that the hydrogen hyperoxid. diffuses rapidly and easily through all animal membranes without being decomposed, and also that it destroys the infectious power of chancre and bubo-pus, and of other exudations of the animal body as soon as it comes in contact with them. On account of these properties Dr. Hofmoke (*Wein. Med. Presse*, No. 8, 1887,) made a trial with the remedy in diphtheria. He administered every hour or two a teaspoonful of a two per cent. solution, and besides he lets the patient inhale the same drug by aid of Sigle's apparatus. It is of importance to have the remedy prepared fresh each time. The first effect of the H_2O_2 usually is a slight increase of temperature; an observation which has also been made on healthy individuals when put under the influence of the hyperoxid. of hydrogen. Occasionally it causes vomiting. Thus far H. has treated 50 diphtheria patients with H_2O_2. The number is as yet too small to draw any weighty conclusions, but H. believes that the favorable result, which he obtained in some very grave cases, have to be ascribed to the action of the remedy. As the latter may be easily prepared, and as its administration offers no difficulty, it might be well to give it a more extensive trial.

Aconitine in Neuralgia.

Crystallized aconitine, when properly used, is one of the most powerful remedies in certain kinds of neuralgia. It is most valuable in so-called "essential" neuralgia, especially facial and trigeminal neuralgia. It is best given in the form of granules containing a quarter of a milligramme of crystallized aconitine, or crystallized nitrate of aconitine, the doses being the same. An interval of four hours should be allowed between the doses, the total quantity of the drug administered in the twenty-four hours not exceeding one milligramme. There are forms of obstinate facial neuralgia, however, such as the intermittent variety, which resist the action of aconitine alone, and these likewise prove refractory to quinine alone. In such cases, success may be achieved by combining the two drugs. This may be done in pills as follows:

℞. Hydrobromate of quinine, 10 centigrammes; crystallized aconitine, ½ milligramme.

One pill containing the above quantity of quinine and aconitine to be taken every four or five hours.

Pelada.

M. Ollivier, in the *France Médicale* of February 10th, gives the result of some observations on pelada. He is doubtful as to its being contagious, although it has sometimes appeared successively in children of one family placed under similar conditions. Some modern dermatologists think that pelada originates in the nervous system; iden-

tity of cause may thus produce identity of effect in different members of one family. No microbe has yet been discovered, and inoculations have so far been entirely negative. According to some authorities, the disease is a tropho-neurosis. M. Ollivier relates a case of a child which first showed symptoms of pelada after a prolonged fit of terror. In twenty-five cases of achromatous or pseudo-porrigo decalvans there was no contagion from husband to wife, or from one child to another. Artificial pelada has been produced in a rabbit by section of the posterior branch of the cervical nerve, immediately below the ganglion. M. Ollivier has allowed children affected with pelada to attend the public schools, and has seen no case in which the disease has been communicated.

Nature of Anthrax Poison.

Bacteriology has made another advance. The question has long occupied observers, how the fatal and general disease-producing effect of pathogenic bacteria was brought about. Dr. Albert Hoffa, of Wurzburg, has specially investigated this subject with reference to the anthrax bacilli, and come to the conclusion that these micro-organisms necessitate for their existence, maturity, and development a large quantity of oxygen. They obtain this oxygen from complex chemical combinations already in existence in the human body, and by thus causing their decomposition they give rise to the formation of very toxic substances, which in their turn produce all the clinical and pathological phenomena characteristic of the disease known by the name of anthrax.

As the conditions for the development of bacteria vary greatly, according to early specific micro-organisms, the different species induce the formation of different toxic substances, and the latter vary in their effect according to their chemical composition, and their more or less virulent nature, but they are only altered compounds of already existing bodies in the organism.

Anomalous Form of Typhoid Fever.

At a recent meeting of the Société Médicale des Hôpitaux, M. Danlos related the following anomalous case of typhoid fever. The patient, an intemperate man, aged 29, had previously been affected with pains in the joints. Four days before admission there were signs of gastro-intestinal disturbance, and on the fifth day the joints became swollen and painful. Articular rheumatism was diagnosed, and salicylate of soda was ordered. A few days later, purpura, epistaxis, and hæmoptysis came on, the temperature remaining almost stationary. On puncturing the knee-joint, a clear fluid was obtained, which contained no micro-organisms, and produced no effect on animals inoculated with it. Nevertheless, the patient got worse. The urine contained albumen; the temperature rose to 39° C. (102.2° F.); and death occurred on the eighteenth day. Post mortem examination revealed hemorrhages in the skin, the mucous membranes, and the lungs, but not in the intestines, which, however, in the lower portion presented eschars and extensive ulcerations.

Micrococcus Pyogenes Aureus.

MM. Gabriel, Roux, and Lepine presented to the Société des Sciences Médicales, at a recent meeting, a series of tubes enclosing cultivations of the M. pyogenes aureus, modified by the action of acetanilide. If a mixture of equal parts of agar-agar solution and a watery 1 per cent. solution of acetanilide be inoculated with a dose of M. pyogenes aureus taken from a normal cultivation, the development may be carried out as usual in astove at a temperature of 35.6° C. The area formed by the growing colony is, however, less compact, less thick, more flocculent, and, what is more interesting, does not assume the yellow orange tint after growing for from twenty-four to thirty-six hours, but remains dirty white, and preserves this tint; but a particle of this cultivation transferred to ordinary agar gelatine grows into a colony which regains the ordinary characters and coloration of the micro-organism.

Remedies for Cocaine Poisoning.

M. Martin (*Journal de Médecine*, January 2, 1887,) relates the following case:

A child, aged 18 months, drank the contents of a bottle containing 50 centigrammes of cocaine in 15 grammes of syrup of marshmallow, which had been prescribed for teething pains. Serious symptoms of poisoning came on. Another practitioner was called in, who prescribed syrup of ipecacuanha, which caused slight vomiting, after which a diuretic was given to counteract the effect of the cocaine on the urinary organs. The general symptoms improved, but there remained considerable irritation of the eyes, which ceased on the administration of two spoonfuls of syrup of caffeine. M. Martin asks whether caffeine may be looked upon as an antidote to cocaine. Dr. Schil-

ling (*American Journal of Pharmacy*) mentions that he has found inhalations of nitrite of amyl useful in cocaine poisoning.

The Station of Man Considered Physiologically and Clinically.

Dr. Guy Hinsdale, in the April number of the *American Journal of the Medical Sciences*, presents some interesting observations on the gait and the power of preserving an erect position while standing—technically called station—as factors in forming an opinion of a man's physical condition.

They show that the normal man and woman have an average sway of about one inch in the forward and back line, and three-quarters of an inch laterally. That children sway to a slightly greater extent than adults, and that, both in adults and in children, closing the eyes increases the sway about fifty per cent. An artificial agent, such as ether, simply exaggerates the normal sway. That a law of rhythmical motion governs the sway of man. The cause of this is not yet clear.

Salicylate of Lithia in Rheumatism.

Dr. Vulpian states that salicylate of lithia is more efficacious than salicylate of soda in cases of acute and progressive sub-acute articular rheumatism. It also has some effect in chronic cases when a certain number of the joints are still deformed, swollen, and painful. 4 to 4½ grammes, and even 5 grammes, may be given in the day. If the improvement is not lasting, 50 centigrammes may be added to the daily dose. Sometimes, when the dose is increased to 5 or 5½ grammes, symptoms of intolerance begin to be shown. Salicylate of lithia may be given dissolved in water, in powder, or in unleavened bread, during or after meals, in doses of 50 centigrammes. The physiological effects of the drug are headache, giddiness, and deafness.

New Bi-polar Electrode.

At a recent meeting of the Academy of Medicine, of Paris, M. Dujardin-Beaumetz presented, in the name of Dr. Apostoli, a new bi-polar electrode. This instrument consists of a slightly conical ball made of gas-carbon (or platinum), divided longitudinally into halves, which are isolated one from the other by a thin strip of gutta-percha; each half of this ball is connected through a long stem to the poles of a battery. The object of the instrument is to limit the action of a current to a given point of the skin or mucous membrane; to utilize all the current circulating between two poles that cannot be corroded; and to make the use of galvano-cautery more general in practice.

Colchicine.

At a recent meeting of the Academy of Sciences, MM. Mairet and Combemalle communicated the results of their researches on the effects of colchicine. This drug acts, according to the dose, either as a diuretic or a purgative. The effects produced are more rapid when colchicine is administered subcutaneously. The dose should be from two to three milligrammes to produce diuresis, and five milligrammes when given as a purgative. Colchicine increases the excretion of uric acid, and diminishes the quantity of uric acid in the blood. Its accumulation in the system, however, and its highly poisonous nature, make it necessary to use it with caution.

Cure of Cirrhosis.

At a recent meeting of the Société des Hôpitaux, M. Féréol again showed a well-marked case of cirrhosis, in which a cure which had already lasted for some months had been effected. M. Rendu mentioned the case of a young officer who, after fourteen punctures, appeared thoroughly cured of this disease. M. Troisier thought that in such cases the diagnosis could not always be relied upon. M. Juyot related a case which had come back to him after two years of perfect health following the first attack. The second attack was accompanied by anasarca, and all the symptoms of cirrhosis, from which the patient finally died.

Stays and Movable Kidneys.

Referring to the remarks of Dr. A. Myers (*Journal*, December 11, 1886,) and Professor Graily Hewitt (*ib.*, January 15, 1887,) on the effect of tight-lacing in producing flexions of the womb, Professor V. A. Manasseïn writes (*Vratch*, No. 8, 1887, p. 206,) that he has collected a large number of cases that confirm the fact that movable kidneys are met with, other conditions being equal, in women who wear or have worn stays, far more frequently than in those who have never done so. This is true in regard both to nulliparæ and child-bearing women.

Condurango Bark.

Dr. Riess (in the *Berlin. Klin. Woch.*, No. 10, 1887), devotes a long article to the

efficacy of condurango bark in cancer of the stomach. It appears that a remarkable increase in weight often follows the taking of this drug. One patient gained 12 kilogrammes (26 pounds) in 83 days, another 15 kilogrammes in 36 days. The appetite improves, vomiting is lessened, and soon allayed altogether, and the pain is almost always mitigated. Cases are given which seem to point to diminution of pyloric thickenings.

Nematode Worms in Beet-root.

At a recent meeting of the Academy of Sciences, M. Girard communicated his researches on the propagation of nematodes in beet-root. These worms, which cause the plant to decay, are probably propagated by means of the manure from animals that have been fed on the roots containing the worm. M. Girard has found that nematodes may pass through the digestive canal of animals without being injured.

Phosphate of Lime in the Night-sweats of Phthisis.

Dr. Rebory has lately published the results of his experience in the use of phosphate of lime in the night-sweats of phthisis. There can be no doubt that the drug has a special effect on the secretions, although the mode of its action is obscure. Phosphate of lime has the advantage of not being at all poisonous; it is easily administered, is well borne by the stomach, stimulates nutrition, and prevents diarrhœa.

Castration and Rabies in Dogs.

In the *Novorossïisky Telegraf* of January 13, 1887, M. Karzo, a South Russian landowner, asserts that castrated dogs never contract rabies. The statement is based on observations made by himself and other persons with like opportunities.

Correspondence.

A Case of Fœtal Umbilical Hernia, without the True Hernial Coverings.

Eds. Med. and Surg. Reporter:

On the morning of March 9, 1887, I was hastily summoned to the bedside of Mrs. T. G., æt. 27, who was in her fourth confinement. An examination revealed a R. O. P. position, and the head in the superior strait, and in a few minutes the child was born.

An examination of the child revealed a large tumor, the size of an adult fist, situated over the umbilicus. The tumor had no covering except a thin transparent membrane (the peritoneum), through which could be seen the large and small intestines. There was an entire lack of development of the abdominal parietes, two inches in diameter, around where the umbilicus ought to be. The cord was attached to the lower margin, and to the right side of the tumor. The child lived three days, having several operations of the bowels, took nourishment, but would not nurse, and died from a general peritoneal inflammation. No attempt at reduction was made.

The mother all the time during her gestation was in good health, but her surroundings were such as she had not been used to, having recently moved into a house which was cold and damp, causing her a great deal of mental worry on account of her children, who were almost constantly sick from the bad hygienic surroundings.

J. S. Hackney, M. D.

Uniontown, Pa.

A Proposition to Translate and Publish the Medicine and Hygienic of the Talmud.

Eds. Med. and Surg. Reporter:

Ever since the publication of my address on "Jewish Hygiene and Diet, the Talmud, and Various Other Jewish Writings Heretofore Untranslated," delivered before the American Medical Association in 1884, at Washington, D. C., I have constantly been urged by the profession to translate and publish the medical and hygienic portion of this "wonderful" compilation, the Talmud. I therefore beg to state to the profession at large that I have concluded to translate and publish from the Talmud everything relating to medicine, providing that prior to my undertaking I can receive one thousand subscribers for the book. Such subscription may be addressed to me in the following words:

"I, the undersigned, agree to take one (or more) copy of the Talmudic Medicine of Dr. von Klein, which shall not exceed $5.00 in cost for Five Hundred octavo pages, or at $1.00 per each hundred pages, payable at delivery."

Under no other circumstances will I ever undertake this labor, which must be traced from "hundreds of thousands of copies," and which has heretofore not been accomplished by any living man. No more will be published than the number subscribed, and fifty extra copies for distribution to the principal medical journals for review. I

shall be glad if other medical journals copy this notice.

CARL H. VON KLEIN, M. D.
110 *E. Second St., Dayton, Ohio.*

Painful Menstruation.

EDS. MED. AND SURG. REPORTER:

Having found the following formula a good one in cases of amenorrhœa and dysmenorrhœa, I send it for publication, thinking perhaps some of your readers might be seeking for something of the kind. It is *not* a specific, but the nearest approach to it of anything I have ever found for the above-named difficulties. *For a four-ounce mixture:*

℞. Fl. ext. cimicifuga, ℥ss.
Fl. ext. pulsatilla, ℥ss–j.
M. Flavor to disguise the taste.
Sig.—One teaspoonful every one or two hours to six doses, unless flow is sooner established.

To disguise the taste, I ordinarily add the following:

℞. Fl. ext. Yerba Santa, ℥j.
Syrup simp., ad. ℥iv.

I find the recipe of most use in women of a nervous temperament. Of course, if there is any self-evident cause for the menstrual trouble, that should be removed; but we often find the trouble existing in young girls in whom the flow is imperfectly established, and who will not consent to an examination.

Hoping others may have the success with this that I have had, I will only add that the formula is not original with me, but given me by a fellow practitioner, and it may have been published before.

Whetstone, O. A. A. NEFE, M. D.

Effects of Quinine.

EDS. MED. AND SURG. REPORTER:

In your issue of the 19th ult., you ask, "Has quinine ever killed anybody?" During the late war I was in charge of a steamer, and while coming from Hilton Head to New York was taken ill. I directed the hospital steward to dissolve a tablespoonful of Rochelle salts in a tablespoon of water. I swallowed the whole at a draught, and at once said, "That is morphine or quinine." Upon investigation we found the labels had been transposed. The salt was marked "Quinine." There was no bad effect from this large dose. The motion of the steamer and the noise of the wind through the rigging obscured cerebral symptoms, if any existed.

Respectfully yours,
WM. A. SMITH, M. D.
Newark, N. J.

Soothing Mixture for Consumption.

EDS. MED. AND SURG. REPORTER:

Of all the mixtures for stimulating the consumptive patient, allaying his cough and quieting his nervousness, I have found none equal to the following:

℞. Syrup liquorice root, ℥j.
Aromatic syrup rhubarb, ℥ss.
Fluid extract of opium, ℥j.
Liquor ammon. acetat., ℥v. M.
Sig.—Shake well. Dose—A tablespoonful every two or three hours.

Patients become very fond of this mixture, and it in no wise interferes with the stomach or appetite. Should constipation ensue, it is easily overcome by an occasional dose of comp. liquorice powder.

J. B. JOHNSON, M. D.
Washington City, D. C.

NEWS AND MISCELLANY.

Abdominal Section Statistics in Kieff.

Professor Rein, of Kieff, in a paper read at the recent Moscow Congress, gave the results of the ninety-five cases in which he had performed abdominal section from 1883 to 1886. Of these, sixty were ovariotomies, with four deaths; twelve were for removal of large cysts of the broad ligaments, with one death; fourteen for myomata, with three deaths. The remaining nine, viz., three exploratory incisions, one enucleation of a cyst in the broad ligament, one section of a purulent abdominal cavity, one section of a purulent cavity in the pelvis, one castration (*kholoschenie*), one ovariotomy with excision of cancerous omentum, one removal of an echinococcus of the omentum—gave three deaths. The causes of the eleven deaths are thus stated: Purulent peritonitis, four; gangrene of the pedicle, one; gangrene of the remaining part of the tumor, one; erysipelas of the leg, one; exhaustion, one; effusion of blood into the pelvis and acute nephritis, one; sepsis, one; and carbolic acid poisoning during the operation, one. The general percentage of fatal cases was therefore 11.5. Professor Rein remarks that he has tabulated every case he had, without making any exceptions, though two or three of the patients were almost moribund when the operation was performed. The arrangements of the hospital wards, too, were far from being satisfactory. Regarding the operations themselves, some difficulty is usually experienced with the sub-peritoneal or connective-tissue cysts. He, however,

had always succeeded in getting them away entire, enucleating them from under the peritoneum, or cutting them out from the broad ligament. He does not agree with Schroeder's plan of washing to prevent hemorrhage, but recommends instead the ligature of the ovarian and uterine arteries. He practiced drainage in nine cases, using india-rubber tubes passing through the vagina in three and glass tubes passing through the abdominal wall in the other six. These glass tubes are twelve millimetres in diameter, and are shaped like a tracheotomy tube. The later operations show a decidedly lower mortality than the earlier, owing to various improvements which have been made in the wards, rendering them less septic. Though Professor Rein recognizes the importance of antiseptic measures, he is quite alive to their possible dangers. Latterly, he has contented himself with disinfecting the room, instruments, air, and operator's hands, not applying any disinfectant directly to the surface of the wound, and not irrigating it. The instruments and operator's hands were washed in simple boiled or sterilized water.

Researches on the Refraction of the Eye in Stockholm.

Professor Johann Widmark has recently concluded a long series of researches upon the state of the refraction of the eye in the schools of Stockholm, and he has had the opportunity of examining 704 males and 742 females. The results he obtained were as follows: In the first schools, comprising children from six to seven years of age, there was no myope. In the second set of schools, comprising girls from eight or nine years of age, there was only one myope. In the corresponding school for boys the myopes had risen to fourteen per cent. This difference is probably due to the fact that the boys have to undergo a special examination for entrance into the first class of the secondary schools, and are consequently compelled to work harder in the preparatory school. At the age of sixteen, when female education usually ceases in Swedish schools, thirty-three per cent. of the girls were myopic, the mean amount of myopia being −2.5 D, which was about equal to that of the boys at the corresponding age. In the higher schools the girls proved to be more frequently and more highly myopic than the boys, the proportion being 54.28 per cent. with an average of —3.3 D, although the girls' schools took from one to two years' more time over the same subjects. The maximum frequency of myopia, 66.67 per cent., occurred in of girls' school, and the maximum amount a myopia, —4.16 D, also occurred in a girls' school, which seems to show that an excess of work for the eye is more injurious to girls than to boys. This depends in part, perhaps, upon the greater feebleness of the girl as compared with the boy, but it is in part due to the fact that in leisure hours the girl occupies herself with handiwork requiring close attention, and with music. Moreover, the means of physical education are very inferior in schools for girls, and gymnastic exercises are either not at all or very insufficiently practiced.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE THREE WEEKS ENDED APRIL 9, 1887.

Long, W. H., surgeon. Leave of absence extended five days, March 23, 1887.

Urquhart, F. M., passed assistant surgeon. Relieved from duty at Norfolk, Virginia; ordered to Washington, D. C., special duty, March 22, 1887.

Pettus, W. J., assistant surgeon. When relieved by passed assistant surgeon Guiteras, to remain at Charleston, S. C., waiting orders, March 24, 1887.

Urquhart, F. M., passed assistant surgeon. To assume charge of Cape Charles quarantine, March 29, 1887.

Norman, Seaton, assistant surgeon. To report for duty at Cape Charles quarantine, April 2, 1887.

Bailhache, P. H., surgeon. Detailed as chairman Board of Examiners, to meet in Washington, April 25, 1887, April 4, 1887.

Purviance, George, surgeon, detailed as member Board of Examiners, to meet in Washington, April 25, 1887, April 4, 1887.

Godfrey, John, surgeon. Detailed as recorder Board of Examiners, to meet in Washington, April 25, 1887, April 4, 1887.

Irwin, Fairfax, passed assistant surgeon. To proceed to Baltimore, Md., on special duty, April 8, 1887.

Pettus, W. J., assistant surgeon. To proceed to Norfolk, Va., for temporary duty, April 4, 1887.

The Cholera in Buenos Ayres.

A local paper from Buenos Ayres in February says: "The public health is no longer a subject of great anxiety, although cholera still lingers in this city and in many other parts of the Republic. The disease is wast-

ing away gradually, and has lost much of its epidemical force. It has disappeared from Rosario, Cordoba, and Mendoza, is gradually wearing away in Tucuman and northern provinces, and continues more or less stationary in this city and in Montevideo. Chili has also been invaded by the epidemic; the disease is raging with terrible effect in the Chilian departments of Aconcagua, Andes, and Quillota. The daily mortality in Santiago, the capital, has been and continues to be heavy. It is noteworthy that both here and in Chili the epidemic has attacked the poor class only. There is no doubt that cholera is dying out rapidly in this city, but the disease is not abandoning the country as fast as we might wish.

Local Boards of Health.

The State of Maine has passed an act approving local Boards of Health, framed as follows:

"There shall be a local Board of Health in each city and town in this State, to be composed of three members, anything in the charter of such city to the contrary notwithstanding."

"Their appointment should be as follows: On the second Monday in April, one thousand eight hundred and eighty-seven, the municipal officers in each town shall appoint three persons, one for three years, one for two years, and one for one year, and thereafter annually before the 15th day of April, one person to serve three years, and each to hold office until another is appointed in his stead. Any vacancy arising from any cause shall be filled at the first meeting thereafter of the municipal officers. If for any reason the appointments are not made at said dates, the same shall be made as soon as may be thereafter."

Gastrotomy in Italy.

The *Gazetta degli Ospedali* of February 23 gives the details of a gastrotomy performed by Professor Loreta, of Bologna, on account of severe pain suffered by a young woman who had swallowed a large quantity of needles with the intention of committing suicide. On searching the stomach carefully with the hand, few needles could be found. The cause of the pain and suffering was explained by further search and extension of the abdominal incision to the right over the liver. The points of several needles were found protruding above the surface of the margin of the left lobe of the liver, and these were deemed to be the source of pain. Some were withdrawn, but others were so fragile that they broke off. The wound in the stomach and in the abdominal parietes was accurately sutured, and the patient recovered without a bad symptom, entirely freed from her suffering.

Small-Pox in Mexico.

Owing to the existence of small-pox in Mexico, and to prevent its introduction into the United States, the Secretary of the Treasury, upon the request of the Board of Health of the State of California, has authorized the appointment of sanitary inspectors, to serve under the direction of the Supervising Surgeon-General of the Marine Hospital Service, at Yuma, Nogales, Benson, and Albuquerque, to assist and co-operate with the State and local authorities in the inspection of passengers and baggage, etc., at the places named.

Hydronaphthol.

A pamphlet with a full description of this new disinfectant and antiseptic may be had without charge by dropping a postal card to Messrs. Seabury & Johnson, 21 Platt street, New York city.

Items.

—At a meeting of the Knox county, Ohio, Medical Society, March 23, resolutions of respect were adopted to the memory of the late Dr. John W. Russell.

—Dr. A. G. Ely, of Girard, Pa. committed suicide March 27th. He was 67 years of age, and somewhat weakened in mind; although quite prosperous, he suffered melancholia from imagined losses.

—Mr. W. Watson Cheyne, in the April number of *The American Journal of Medical Sciences*, in a very timely article, fully describes the technique of the methods of investigating bacteria, including the study of their characters by the aid of the microscope.

—Dr. Charles B. Hough, a graduate of Jefferson Medical College, and Dr. Mary Paul Hallowell, of Horsham, Pa., a graduate of the Woman's Medical College of Philadelphia, were married by Friends' ceremony in their new home, Ambler, Pa., on Thursday evening, March 10. Dr. Mary Willits, of Philadelphia, acted as bridesmaid. They will jointly practice their profession, and will, on account of their ability and past experience, succeed in establishing a large practice in their new field of labor.

SOLUBLE
PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1054-1556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant. Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

DOUBLE DISEASE OF THE AORTIC VALVES—CARDIAC INCOMPETENCY.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

BY WILLIAM PEPPER, M. D., LL. D.,

Provost of, and Professor of the Theory and Practice of Medicine and of Clinical Medicine in the University of Pennsylvania.

Reported by William H. Morrison, M. D.

Gentlemen: I wish to call your attention to-day to a chronic form of cardiac disease. This man is fifty-two years of age, a resident of this city, and an engineer by occupation. He came to the hospital three weeks ago. His parents died of old age, and his brothers and sisters are all living and in good health. He had the ordinary diseases of childhood, and at the age of sixteen had small-pox. He states that when a young man he had a chancre and also gonorrhœa. He is married, and is the father of sixteen children, eight of whom are living. For five or six years he was accustomed to run foot-races, taxing himself in this way very severely. When the war broke out he enlisted and served four years. He received some wounds and had camp diarrhœa. After the war he became an engineer. About this time he was struck on the head and received a compound, depressed fracture of the skull, for which he was trephined, and made a good recovery, the only disagreeable effect left being slight impairment of the memory. Two years ago he discharged a lumbricoid worm by the mouth. In May, his left shoulder was dislocated. About one year ago, shortness of breath with a burning pain behind the sternum was noticed.

The history, then, is one of great exposure and severe exertion. The man has been accustomed to drive himself, so that he was constantly under a strain, and this was particularly the case when he was running so many foot-races. I refer especially to this, as it may have a possible bearing upon the condition which has since developed. He began two years ago to suffer with dyspepsia, and while in this condition, with weakness and shortness of breath on exertion, he went to work in a deep mine, running a pumping engine, and for four months was almost constantly wet to the skin. The pain, shortness of breath, and dyspepsia grew worse, and he was compelled to give up the work. The attacks were violent and were brought on by exertion. At times these attacks of pain in the sternal region would occur as often as four or five times a day. He has done no work for the past six months. The attacks have continued to recur with increasing severity, and he has been compelled to stand for five or six hours at a time in order to relieve the pain. Swelling of the hands and feet was first noticed four months ago. Since then œdema has appeared on several occasions, but has not continued. Two months ago he came to this city, and was admitted to another hospital. There was at that time expectoration of blood-tinged mucus and marked shortness of breath. Under treatment, he improved and left the hospital, but again growing worse, came to this institution two weeks ago. The attacks of pain seemed to come on without any exertion. While they often occur when he is careful in regard

to his diet, they are distinctly worse when he is imprudent. The pain is felt to the left of the sternum, but it never goes up to the shoulder or down the left arm. The spells of pain have been distinctly præcordial.

He has a well-made chest. On percussion, the resonance is good. On auscultation there is no marked change in the breath sounds. The pulse is 80 per minute, regular, with a sharp rise and a quick fall. The sphygmographic tracing of the pulse taken yesterday, shows that the line of ascent is sharp, the summit is almost normal, but the fall is abrupt and the secondary rise resulting from the closure of the aortic valves is almost entirely wanting. There is visible pulsation in the arteries of the neck. The apex beat of the heart is very diffused, it extends outside of the nipple line and as far down as the seventh rib. The impulse is distinctly transmitted to the epigastrium. There is no prominence of the præcordium. Palpation shows that the impulse is diffused, but not powerfully. Percussion shows enlargement of the area of superficial dullness in a direction downward and to the left. On deep percussion the cardiac dullness is found to extend one inch outside of the nipple line and below the normal position. It does not extend above the third interspace, and does not extend beyond the median line of the sternum. There is, apparently, no dilatation of the auricles, and very little affection of the right ventricle. There is marked enlargement only of the left ventricle.

On auscultation at the base of the heart a strong double murmur is heard. The two elements are almost alike, sounding like the whispered "who," but the diastolic murmur is the stronger. Tracing these to the body of the heart and the apex, they lose in force rapidly, and at the apex a new murmur is heard quite distinctly. This would indicate that the murmurs heard at the base originate at the aortic orifice. In time, the murmur heard at the apex is systolic, high-pitched, and shrill, totally differing in quality from those heard at the base. It is carried into the axilla and is audible at the angle of the left scapula. This murmur is due chiefly to mitral regurgitation. The diastolic murmur is also heard at the point of the heart, and is slightly audible toward the axilla. There is no reason to think that there is any mitral stenosis, for the diastolic element at the apex is like that at the base. The point of greatest intensity of the basic murmurs is mid-sternum, opposite the second interspace and at the junction of the second costal cartilage with the sternum. The line of greatest transmission is upwards and to the right. The murmurs are heard in the carotid arteries, where the two murmurs, as is usual, unite in one. They are also heard in the subclavian arteries. The diastolic murmur is heard as low as the xiphoid cartilage. These are perfect illustrations of aortic murmurs. Pursuing the murmurs down the sternum, we find that the diastolic murmur is most strongly carried, but that the systolic murmur is also heard. We have then aortic stenosis with aortic insufficiency.

We shall consider the exact condition induced by these lesions, the exact condition of the aorta and of the arteries, and the nature of the process that has brought about these lesions. As a result of the aortic stenosis, the left ventricle is compelled to act with unusual force to overcome the obstruction. Increased force is also required to overcome the mitral leakage. The compensatory hypertrophy has not been perfect, and the circulation is not well kept up. We have not a powerful impulse. Although the area of the impulse is increased, its force is not considerable. As a result, there has been œdema of the feet. The dyspnœa is due to want of proper force in the pulmonary circulation. The pain which is experienced on excitement or exertion is the pain of cardiac incompetency. These pains are not only proof of the cardiac incompetency, but they are connected with a special condition of the nerves and ganglia of the heart. They are significant of want of proper compensation. We know, therefore, that this man has dilated hypertrophy of the left ventricle, without sufficiently increased strength of the walls of the heart to fully compensate for the effects of these lesions. Fortunately he has not had such serious trouble in the lung as to cause damming back of the blood upon the right cavities of the heart, thus inducing dilatation of the right ventricle. The only suggestive thing in that direction is the pulsation below the xiphoid cartilage. This, however, is not sufficient to indicate much dilatation of the right ventricle. As the area of cardiac dulness does not extend much beyond the right edge of the sternum, and as there is no distension of the jugular veins, showing that they have no difficulty in pouring their blood into the right auricle, we may infer that the right cavities have not suffered to any marked extent, but that the lesions are confined chiefly to the left cavities, and especially to the left ventricle.

The next point is in reference to the exact condition of the aortic valve, and to the

condition of the aorta; whether there is disease of its walls or whether there is dilatation. We observe that here is visible pulsation of the subclavian and carotid arteries, and the fingers placed upon these vessels receive a strong impulse, suggesting that they are dilated. The arch of the aorta is not dilated sufficiently to force itself to the surface and enable us to recognize it by an increased dullness. It is well covered by the lungs, which appear to be somewhat emphysematous, and this may serve to explain some of the dyspnœa. We are not able to positively determine that there is dilatation of the aortic arch. The radial arteries are distinctly large and hard. If the arteries at a distance from the heart present decided changes, we may be sure that those near the heart are similarly affected. The strength of the murmur as heard over the course of the aorta suggests very forcibly that the lining of the aorta is roughened with patches of atheroma.

It is a difficult question to decide the exact cause of the cardiac and arterial changes in this case. It is to be noted that despite the many conditions which the man has presented, he has never had rheumatism, nor is there any evidence that the cardiac disease began with any acute constitutional process. It is in all probability a chronic local trouble, and this man has been subjected to several causes which would be likely to induce disease of the heart and of the arteries. In the first place, there is a possibility of syphilis. Although the man appears to have presented no secondary lesions of this affection, yet we cannot exclude it in considering the causation of this trouble—for syphilis is a fruitful cause of disease of the arterial walls and of the cardiac valves. In addition to this, he has led a life of severe muscular exertion, conjoined with extreme exposure to hardship, damp and bad hygienic conditions; all of these things are calculated to strain the arterial coats and set on foot irritation and a low grade of disease which would run into chronic endarteritis and chronic valvulitis. Whether the conditions present are the result of syphilis or whether they come from slow, degenerative changes, probably dating back many years, we cannot say. This case serves to illustrate the way in which cardiac disease often develops in persons who have led lives of exertion and exposure. We are to note that in this case, unlike those which arise acutely, where the mitral valve is more likely to be affected, it is especially the aortic valves and the arterial coats which are involved. The mitral lesion may be purely secondary, resulting from the stretching of the ventricle until the auriculo-ventricular orifice is so much dilated that the valves are not able to close it.

Where there is this extensive change in the coats of the artery, it often happens that we find that the arteries of the kidneys suffer, that the interstitial tissue of the kidney undergoes irritative changes, and that the organs pass into a condition of sclerosis, with thickening of the interstitial tissue, thickening of the arterial tunics, changes in the blood-pressure and œdema, and associated with these, changes in the epithelial lining of the tubules, although this is often absent. Examination of the urine in the present instance, shows that its quantity varies from sixty to eighty ounces, the specific gravity has been from 1012 to 1020, it contains a trace of albumen, and the microscope shows a few hyaline and faintly granular casts. This man has a certain degree of contracted granular kidney, and this condition is often associated with this type of aortic and arterial diseases.

Examination of the eyes shows atrophy of the optic discs. The vessels are small, and there are patches of pigment indicating that the arterial coats have been involved, and that there is a tendency to irritative changes in the fibrous tissue leading to contraction and pressure upon the enclosed structures and interference with nutrition.

I shall next speak with reference to the prognosis and treatment. The changes have advanced so far, that a cure of course is impossible. The man must lead a life strictly adapted to the organic changes present. He must avoid excitement, excesses, and sudden exertion. The dilated heart needs strychnia and digitalis. The diseased arteries should be treated with iodide of potassium, and on account of the possible syphilitic element, mercurials should be used from time to time. The diet must be regulated. In order to relieve the attacks of pain, nitro-glycerine or nitrite of amyl should be employed. Under favorable conditions, with such a course of treatment, we can not put any limit to the time that this man may live, and live comfortably. This is a most chronic process, and years may pass and the man be as well as he is now. Œdema will come and go, and attacks of threatened cardiac failure will appear, but this may be overcome by a stimulating and tonic treatment. If, however, he exposes himself, contracts cold, and exhausts the heart, the compensation which is now imperfect may be broken, and the man may hasten his end to any ex-

tent. His life depends upon the care with which he pursues the plan of treatment which has been indicated.

COMMUNICATIONS.

INJURIOUS INFLUENCES CAUSING DEAFNESS.

BY LAURENCE TURNBULL, M. D.,

Of Philadelphia.

The following may be mentioned as the most prominent causes:

Alternate heat and cold, when suddenly applied to the ear, are very injurious, and these alternations of temperature, combined with dampness, produce what is termed an influenza, or common cold, or cold in the head, which is sure to produce inflammation in the ear, and the repetition of this same cold alternately produces a diseased condition of the ears, which, by its alternations of tissue, both of the receptive, mechanical, and nervous apparatus, terminate in a form of acoustic deafness, the most prevalent and difficult to cure, or even relieve, unless seen in its very early stage.* There are also diseases of the auditory nerve of hearing, which will readily be understood from the character of the nerve of the ear, as reflex irritation and inflammation from various diseases, hemorrhagic inflammation of the cochlea, hemorrhagic inflammation of the labyrinth in children, primary acute purulent inflammation of the labyrinth resulting in meningitis, otitis labyrinthica, acute inflammation of the membranous labyrinth, cerebro-spinal meningitis, disease of the auditory nerve and its terminal parts, syphilitic disease of the labyrinth, traumatism involving the internal ear, atrophy of the labyrinth, changes in the auditory nerve from typhoid, scarlet, and other fever, also from variola, diphtheria, and mumps. It may also be comprehended how deafness can be an inheritance through a diseased father and mother. Yet the deafness which is charged to this cause is not as frequent as we would be led to suppose by the imperfect statistics of our institution for the instruction of deaf-mutes. A large number of cases of loss of hearing are developed during the period of infancy, when changes in the organs of hearing may occur, the result of colds, measles, whooping-cough, scarlet fever, and cerebro-spinal meningitis. The ear is so apt to be overlooked in the great anxiety for the life of the child. When the crisis is over, then the poor, damaged ear is perhaps examined, only to find the child profoundly deaf. No one can fully understand the importance of hearing, both for social intercourse and educational development, until some dear one has lost it. It is an important matter that obstetricians and nurses should be carefully taught some knowledge of the anatomy and pathology of the ear, as the deafness of many of the so-called congenital deaf-mutes is the result of mucous, cheesy matter or blood in their meatus or in the tympanic cavity at birth. Another cause is physicians not attending in time to catarrhal deafness, the result of cold from exposure or teething. The nurse is often at fault in placing the ears of the infant in draughts of cold air, and allowing cold water to enter the meatus, and pass back to the membrane, lodging there and causing acute inflammation, shown by intense pain and persistent earache, not relieved until perforation of the drum-membrane takes place or extension to the internal ear or brain.*

It has already been shown that there are two distinct ways of hearing—one by the transmission of vibrations of air through the tympanum, ossicles, fluid in the internal ear to the nerves; the other by a similar transmission of vibrations through the bones of the head to the petrous portion of the temporal bone, and finally reaching the nerves. The explanation of this is that the waves of sound being propagated in every direction, when they reach the tympanic cavity pass out, in part, through the conducting mechanism of the ear, and whenever this conducting mechanism is in its normal condition, are lost to our perception; if, however, this mechanism offers more resistance than normal, as in acoustic deafness, from immobility due to thickening, calcifications, etc., a part of the sound which normally passes out and is lost is reflected back to the nerve of the ear. Any person can make experiment on themselves in producing acoustic deafness by closing one meatus with the finger, and then testing with the tuning-fork; the closing of the meatus setting up the same sort of resistance as is offered by the calcified or thickened drum membrane. The object of artificial aids of hearing is so to intensify the waves of sound, another way of hearing, that they can overcome the resistance opposed by these diseased conditions. The different forms of ear-trumpets and conversation-tubes are calculated to bring about this

*Imperfect Hearing and the Hygiene of the Ear, 3d ed., p. 99.

*Manual of Diseases of the Ear, 2d ed., p. 444.

intensification of the waves of sound for cases of acoustic deafness. According to the census of 1885, there were in the United States some 35,000 deaf mutes, and but a small part of them were being instructed at all, there being only about twenty-five institutions in the United States in May, 1868. In only eleven is articulation or lip reading the method employed. These schools contain only 430 pupils out of the 7,801 that are taught the sign language, or combined method.

To be able to mitigate, even in a slight degree, the distressing condition that this form of deafness implies, is to confer an inestimable boon on the sufferer. By the persistent and repeated exertions of one eminently distinguished as a teacher and friend of the deaf in the largest institution for the education of this class in this country, considerable progress has already been made in this direction.*

Twelve cases are reported that have been not only able to hear, but to repeat vowel sounds; and some of these pupils can already carry on quite an extended conversation by the aid of a flexible conversational-tube of special design. This tube is about four feet in length, made of wire wound in concentric circles, incorporated in rubber, around which is woven a mohair covering.

The next mode by which we hear is by what may be termed external touch, and the use of the organ of speech is acquired solely by the aid of the other senses. Sound is, therefore, neither the sole nor the primary element of voice. It is the breath set in motion by the lungs, and reduced to sonorous vibrations by passing through the glottis, which resembles the reed of a musical instrument. It is composed of rapid undulations which pass forward from the glottis, and are reverberated and modified by the organs of speech. The finger-touch of a deaf mute on our glottis can, without any previous instruction, detect these vibrations, and at once he obeys the natural impulse to produce similar vibrations. Arnold† has devoted much careful study to this subject of teaching the deaf mute to speak, stating, as is well known, that children who lose their hearing, soon lose their speech, because touch and its habits are not so fully confirmed, nor is the control of the will over the organs so perfect as in riper years. In all such cases no time should be lost in providing a teacher under whose skillful directions the speech may be kept up to its normal condition.*

SOLUBLE COMPRESSED HYPODERMIC TABLETS.†

BY H. AUGUSTUS WILSON, M. D.,
Of Philadelphia.

A little over six years ago I called the attention of the profession to soluble compressed tablets for hypodermic use, which I had originated some four months previously, to take the place of prepared solutions and powders, with which I had become dissatisfied.

My first paper on the subject, read before the Philadelphia County Medical Society, in October, 1880, simply called attention to their utility, and I exhibited a single formula to prove the practicability of the method. The various steps taken to obtain a convenient form, the necessary accuracy of dose, and the proper disintegrator, were all stated in my second paper, read before the American Medical Association, May 5, 1881, and it is not necessary to do more than refer to them at this time.

Where an infinitesimal amount of active drug was to be used, such as digitaline, atropia, strychnia, hyoscyamine, and other such active agents, the dose of which is from the one-sixtieth to the one-two-hundredth of a grain, it was found necessary in order to compress them to add an excipient or disintegrator. It was only after a series of very thorough and continued experiments that the sulphate of sodium was adopted for this purpose—a neutral salt, one readily soluble, having no irritating or medicinal action, with which the drug was incorporated when the tablet to be compressed did not contain more than one-twelfth of a grain of the active agent.

The salt has been found to answer every indication. At first its use was advised in all the tablets, but upon further experience and the wonderful advances and improvements in the mechanical appliances, I found it unnecessary, except as stated above, where the active agent is less than one-twelfth of a grain. The morphia salts, which are more largely used than any other in hypodermic medication, gave some trouble at first, in their tendency to harden if kept for a consider-

† Read before the College of Physicians, Philadelphia, January 5, 1887.

able length of time. This difficulty, however, has been entirely overcome by improved manipulation and experience in compressing.

A solution is usually accomplished in from fifteen to thirty seconds by the method I usually employ, which is to drop a tablet into a teaspoon containing fifteen or twenty minims of warm water. It is then crushed with the end of the syringe, to which the needle is attached, and drawn up and forced out two or three times by the syringe, when a perfect solution is obtained. I have on my syringe a small cap with a smooth surface fitting on the needle end, which is useful in keeping the syringe in a good condition, and is a most convenient pestle with which to crush the tablet.

Let it be borne in mind, that these tablets are in reality nothing but powders put in a most convenient, accurate, and portable form, and it will be apparent that no special syringe is required.

Any ordinary hypodermic syringe can be used for these tablets, just as readily as for ordinary solutions, whether prepared or made at the time of administration from powders.

I abandoned prepared solutions for hypodermic use because of the penicilium, confervæ, and other low forms of vegetable life, which developing in solutions at the expense of the drug, increase the strength of the solution. Professor Roberts Bartholow, in his work on hypodermic medication, says that the injection of solutions containing these vegetable growths is one of the causes of the hard nodules so often seen. To prevent the formation of these organisms by the addition of such germicides as tartaric, hydrochloric and salicylic acids, is to induce chemical changes in the solutions, and greatly increases the danger of inflammatory deposits at the site of puncture. As, on the other hand, increased strength must be the result of the evaporation of the water, it will be apparent that accuracy of dose is either impossible or very rarely accomplished in the administration of prepared solutions.

In abandoning the use of prepared solutions and adopting powders, I avoided the objectionable features of the former, but could not obtain the desired end of accuracy of dose, as was clearly demonstrated by the accumulation of deposits in the recesses of my pocket-case, due to the sifting of the drug through the interstices of the folded paper. Should moisture gain access to the powder, as it not infrequently does, more or less of the contained drug will dissolve and be absorbed by the paper. The necessity for some other more reliable method became still more apparent, when such drugs as atropine, strychnine, etc., were to be administered in such minute quantities as the $\frac{1}{100}$ or $\frac{1}{200}$ of a grain.

My aim originally was to devise a method by which accuracy of dose might be invariably secured, regardless of the quantity of the drug required, permanence and freedom from change or decomposition, however long on hand, and almost under any circumstances; ready solubility, convenience of administration, and in such a form as to be readily carried on the person.

Since the introduction of this subject to the profession some six years ago, a number of alkaloids have come into general use, and their hypodermic administration is rendered practicable by these tablets. Among them may be mentioned digitaline, cocaine, duboisine, hyoscyamine, picrotoxin, conine, curarine, eserine, physostygmine, caffeine, quinia bimuriatica carbamidata, etc.

The convenience of these soluble compressed hypodermic tablets for hypodermic, ophthalmic, and general use, makes their addition to our armamentarium a decided advantage. These remedies are placed in such convenient form that a physician can carry in a very small pocket case a large number of remedies in their most condensed and active form, ready for use in emergencies, or for the needs of general practice. I have found them extremely convenient in ophthalmic medication, when the method of administering is to insert the desired tablet in the lower conjunctival sac, by drawing down the lower lid. Ordinarily a few minutes at the most are required to dissolve them. No irritation has ever followed or attended their use in my hands, and I am unable to understand how there could be any, for the disintegrator, when any is used, is perfectly non-irritating. They should, in my opinion, be substituted for the bulky changeable solutions in which germicides which would irritate the sensitive conjunctiva are rendered necessary to prevent the growth of minute organisms.

The recent use of some tablets that I have kept for six years clearly demonstrated the fact that their solubility has not been affected in that time.

At the present time the following drugs are prepared:

Morphine, morphine and atropine, atropine, strychnine, apomorphine, pilocarpine, aconitine, morphine bi-mecon., hydrarg. chlor. corros., digitaline, cocaine, caffeine, hyoscyamine, duboisine hydrochlorate, duboisine hydrochlor. and morphine, hyoscyamine sulphate, hyoscyamine sulph. and morphine, picrotoxin, picrotoxin and strychnine, conine

hydrobromate, conine hydrobromate and morphine, curarine sulph., eserine sulph., eserine sulph. and morphine, physostigmine salicylate, quin. carbam. mur.

To sum up, I claim that the advantages of this method over any other known are—

1. The convenient size of the tablets.
2. The immunity from change.
3. Their accuracy of dose.
4. Their certainty and rapidity of action.
5. That they may be used by the mouth, nares, urethra, and rectum.
6. Their adaptability to ophthalmic medication.

SALICYLATE OF HYDRARGIRIUM, AND ITS EMPLOYMENT IN THERAPEUTICS.

BY BRUNO CHAVES, M. D.,

Of the Polyclinica Geral, Rio de Janeiro.

It is with the greatest interest that I contemplate the amazing progress with which, day by day, the great American republic continues to advance on its road to the highest place among civilized nations; and I sincerely regret that there are not closer relations, both commercial and scientific, between that country and the other nations of the American continent, which, more than any other, requires the benefits of American progress.

An ardent admirer of the United States, with which I wish my countrymen to be more intimately connected in every respect, I recently read with much pleasure some valuable scientific articles published in your excellent periodical, the MEDICAL AND SURGICAL REPORTER, a number of which had been kindly lent me by my friend Dr. S. D. Rambo, a citizen of that republic and a conspicuous ornament of the dental profession in this city.

The perusal of these articles excited in me the desire to make known to my professional brethren in the United States some scientific discoveries recently made in Brazil. On my expressing this wish to my friend, Dr. Rambo, he kindly offered to translate my article, and, thus encouraged, I take the liberty of offering you for publication in your valuable periodical a few remarks on the salicylate of hydrargirium and its therapeutic employment, thus contributing towards calling the attention of the profession to a discovery which has proved to be of great utility in medical practice.

In the early part of last year my learned friend, the eminent Prof. Dr. Silva Aranjo, who lectures on cutaneous and syphilitic diseases in the Polyclinica Geral, of this city, received from Dr. Gamberini, of Bologna, Italy, a pamphlet written by this able specialist, in which he treats of the phenate of hydrargirium, and of the success which had attended his experiments with this substance in the treatment of syphilis.

As the syphilis is a parasitical disease, Dr. Gamberini naturally conjectured that the union of two such powerful parasiticides as mercury and phenic acid could not fail to produce a very efficacious remedy. His experiments proved that his conjectures were well founded, for he was very successful in the treatment of syphilis with this mercuial salt.

Prof. Silva Aranjo, for whom I have the honor to be clinical director, kindly allowed me to read the pamphlet of the eminent Italian specialist. In doing so I conceived the idea of causing phenate of mercury to be prepared for our own experiments on *syphilis* and *skin diseases.*

Messrs. Veiga & Delgado, two competent chemists, were intrusted with the preparation of this substance, which in our practice produced results similar to those obtained by Prof. Gamberini.

In a conversation on this subject with Prof. Silva Aranjo, Mr. Delgado suggested the expediency of preparing the salicylate of hydrargirium as well as the phenate; for, as he declared, he had no doubt that the effects of the former would be as satisfactory as those of the latter, and probably still more so. Prof. Silva Aranjo assented, and Mr. Delgado had, I believe, the honor of being the first person to prepare this new salt.

We proceeded, then, under the orders of Prof. Silva Aranjo, to experiment with the salicylate of hydrargirium, administering it in daily doses of 1 milligram (0.0154 grain), which we gradually increased to 25 milligrams (0.385 grain), in pills made of the powder and extract of liquorice. In extreme cases we have given two doses a day.

Our success exceeded our expectations, and from what I have observed I am convinced that the salicylate of mercury will become as essential to therapeutics as the iodide of potassium, calomel, and other useful medicines.

The wonderful results obtained from the employment of this mercurial salt as an internal remedy led us to experiment with its external application (from 50 centigrams to 1 grain of the salicylate of hydrargirium to 30 grams of white vaseline). The success of this experiment was no less striking than that of the internal remedy. We effected cures of syphilitic eruptions and ulcers of a

syphilitic character, which had previously been treated with little or no result with other medicines, including mercurials and iodides, such as ointments of bi-oxide of mercury and iodide of potassium.

We also employed the salicylate of hydrargirium very successfully in urethral injections for gonorrhœa, mixing from 10 to 15 centigrams of the new salt with 200 grams of distilled rose-water, and adding sufficient carbonate of soda or potassium to cause it to dissolve.

Prof. Silva Aranjo, Cr. Carvalho (his substitute), and myself, communicated the result of our combined experiments to a number of physicians of this city, so that salicylate of hydrargirium is now very much used.

I must not neglect to state that Dr. Neves da Rocha and Prof. Moura Brazil have employed this salt so successfully in the collyrium in purulent and even granulous conjunctivitis, as well as in other diseases of the eye, that they prefer it to any other medicine now in use.

These specialists have also been very successful in their experiments with this substance in hypodermic injections on syphilitic patients, their formula being the following; 5 centigrams of salicylate of mercury to 10 grams of distilled water, with sufficient carbonate of potassium to cause it to dissolve.

The effects of this salt are much more rapid and efficacious than any other with a mercurial or iodic base, such as proto-iodide, which is very much used here, bi-iodide, bichloride, phenate and tannate of hydrargirium, as well as the iodides of soda and potassium. It is well received by the stomach, and we saw no instances of mercurial stomatitis, gastritis, or enteritis, resulting from its use.

We have successfully employed salicylate of hydrargirium in the treatment of several cutaneous diseases, such as *marginal eczema of Hebra, circinate pityriasis of Vidal, versicolor pityriasis, parasitic sycosis*, etc., and even *leprosy*, in which we used it internally and externally in connection with gynocardic acid, the active principle of the *oil of gynocordia odorata.*

In an article like this much that is interesting must necessarily be omitted, but before concluding I cannot refrain from referring to the following two cases:

The first is that of a syphilitic patient suffering from an obstinate generalized tuberculous syphilitic eruption, and subject besides to violent rheumatic pains and continuous gonorrhœa.

After experimenting with all the mercurial and iodic remedies usually employed in such cases, and finding them all insufficient, we succeeded in removing the facial eruption by means of the ointment of salicylate of mercury.

The second was a case of syphilitic fungus near the anus, in which it is usual in the hospitals of this city to resort to an operation with the thermo-cautery of Paquelin after giving chloroform to the patient. We, however, succeeded in destroying the fungus by means of an external application of salicylate of hydrargyrium.

In conclusion, I beg to tender my thanks to the editor of the MEDICAL AND SURGICAL REPORTER for the publication of this article, and to Dr. Rambo for kindly translating it.

Rio de Janeiro, February, 1887.

RESUSCITATION OF ASPHYXIATED INFANTS.

BY T. C. SMITH, M. D.,

Of Aurora, Indiana

Dr. E. T. Blackwell, in his brief, practical article in the MEDICAL AND SURGICAL REPORTER of February 19, brings again forward a good method for readily resuscitating an asphyxiated new-born infant, and one that can certainly be done while yet caring for the mother, if she should need immediate attention at that very important moment, which is to her often very critical. Yet, in most cases, the whole attention can be given to the infant if needed. An assistant can place the hand over the uterus and watch the course and conditions of the woman in most cases, while efforts at resuscitation are carried on with the death-threatened infant.

But I write to renew attention to a method brought to notice several years ago, that has served, for me, an excellent purpose in some very obstinate cases of infantile asphyxia. I regret that I do not now remember the one who first brought this method forward. It is very simple. Take the infant by its lower extremities with the left hand, suspend it head downward, then with the right hand embrace the neck posteriorly, using for this purpose the thumb, ring, and little fingers, while the index and middle fingers support the head. Now hold the head and shoulders downward and comparatively still, while with the left hand the body and feet are made to sweep forward and backward from ten to fifteen times or more in a minute, until respiration is established. Each time that the body is bent forward on the face the air is pressed out of the lungs, and when

bent well back again the air enters the lungs freely. Keeping the head downward causes a full supply of blood to be given to the brain. This process does not prevent fanning, or sprinkling suddenly a little cold water on its sides by an assistant if needed for the shock it produces. Cloths wrung out of hot water can also be applied if needed. It is not good practice to lay an asphyxiated infant on its back, for if there is mucus in the mouth or throat this will tend to strangle it. If placed on its side or with the face downward this cannot occur, or, at least, is less liable to do so. If there is enough mucus in the child's throat to cause considerable noise by its rapid succussions in process of respiration, all this will cease in a little time by placing the child face downward, or on its side with the face inclined downward. In this way the mucus will gravitate away from, rather than into, the throat. Of course it can be otherwise removed, but this is an easier and a very ready way to obtain relief from this harassing symptom.

Some have claimed that the Marshall Hall method of artificial respiration will not cause air to enter the lungs of an infant where the respiration has not already been partially established. In the method above recommended, one can readily satisfy himself of the entrance and exit of air into and from the lungs every time the infant's body is well bent forwards or backwards, for the evidences will be unmistakable and easily observed.

Medical Societies.

THE NEW YORK NEUROLOGICAL SOCIETY.

Stated meeting, March 1, 1887. The President, Charles L. Dana, M. D., in the chair.

Presentation of the Cord and Nerves in a Case of Alcohol Paralysis; Multiple Neuritis.

Dr. H. M. Biggs presented the case. Bertha B., aged thirty-five, married, admitted to the hospital, September 20, 1886. History imperfect. Nothing of importance in the history up to the beginning of her present illness, about five weeks before admission, when she began to have sharp, shooting pains in both legs, but more severe in the right. She began to lose power in her limbs, and one week later was unable to walk because her limbs were "too weak." The loss of power seemed to begin in her feet. She complained of pain in her back and weakness when she tried to stand. Later, she began to have pain and lose power in her arms. She says she has been a moderate drinker, and denies syphilis.

On admission, the patient was almost completely paralyzed in lower extremities; could barely raise her limbs from the bed. The muscles of the upper extremities, especially the extensors, were also somewhat affected. There were some spots of hyperæsthesia and partial anæsthesia irregularly distributed over the lower extremities, and also considerable numbness. Sensation in the upper extremities seemed to be normal. The reflexes were lost. There was marked atrophy in the legs and thighs on both sides, particularly of the extensors of the foot, and a moderate amount in the arms. The extensors here were also most affected. She complained of very severe pain in the arms and legs, which kept her awake at night, and there was marked tenderness on pressure. Temperature at 9 a. m., 100°; at 5 p. m., 101.2°; pulse, 9 a. m., 104; at 5 p. m., 112. Urine, 1018; albumen, one-eighth in bulk; no casts.

Two days after admission the patient was found to have a moderate amount of fluid in the right pleural cavity. Twenty-four ounces of serum were withdrawn. She gradually failed, lost strength, emaciated; the pleurisy developed into an empyema, for which a free opening was made in the chest. Before death, which occurred in February, 1887, she had lost all power over both lower extremities, and the arms were partially paralyzed. Atrophy was very marked in both lower extremities and forearms. Pain was constant and paroxysmal, and very severe. Tenderness on pressure and pain on movement of muscles marked. Contraction of the muscles gradually developed until thighs were sharply flexed on trunk, and legs on thighs. Attempts to straighten the limbs caused the most severe pains. The bladder and rectum, the muscles of phonation, deglutition, and respiration, and the nerves of special sense, were entirely unaffected. The reactions of degeneration were present. The patient died of exhaustion resulting from the empyema.

Autopsy.—Patient greatly emaciated. Legs and thighs markedly flexed. Muscles of the leg of a yellow color, and apparently converted almost entirely into fat. Muscles of thigh much less affected. Spinal cord, nerve roots and trunks normal in appearance.

Microscopical Appearances.—Spinal cord

apparently normal, with the exception of slight sclerosis in the columns of Goll in cervical region. Nerve roots normal. In one of sacral nerves before its exit from spinal canal was found a marked increase in the endoneurium, with diminution in the number of the nerve fibres, and an irregularity and indistinctness in these appearances. The right sciatic nerve showed the same changes more marked. In the posterior tibial the process was even more advanced, and in this only an occasional nerve fibre could be detected. Microscopically the gastrocnemius was composed almost entirely of adipose tissue; only here and there atrophied muscle fibres were found. The small nerve trunks in the muscle showed advanced degenerative neuritis, with comparatively little new growth of connective tissue in the nerves.

The president thought that in this case it had been fully demonstrated that the alcohol paralysis was due to a neuritis and not to a myelitis.

Dr. M. A. Starr had seen the specimens, and said there was no question with regard to the existence of neuritis in this case, and the normal condition of the anterior cells of the spinal cord. There was a slight sclerosis in the columns of Goll which he was unable to explain. The same condition had been observed in a case of Hamilton recorded by Granger Stewart. He referred to a well-prepared specimen by Dr. Van Gieson in a case of Dr. Ball's, not yet published; also to the manner of preparing specimens.

Dr. Biggs said that contrary to the ordinary condition found, the process seemed to be more a degeneration of nerve fibre than an interstitial neuritis, especially in the smaller nerves.

Dr. Noyes spoke of the frequent occurrence of amblyopia with alcoholism, and said it was due to a partial neuritis of the optic nerve, referred, as had been shown, to the centre field and not to the field at large. He suggested that in cases like the one reported by Dr. Biggs, the neurologists should make careful examination of the optic nerves. In reply to Dr. Starr, whether scotoma was due as frequently to tobacco as alcohol, he said it might be due to either, but the patients frequently combined the two habits.

The patient said the name alcohol paralysis was rather begging the question. This patient, it seems, had been only a moderate drinker. The same fact had been noticed in other cases.

Abstract of Dr. Stevens's paper on

Irritations arising from the Visual Apparatus considered as Elements in the Genesis of Neurosis.

Two classes of influences were recognized as causes of functional nervous disorders; the remote and the immediate. The remote causes may be sufficient to perpetuate a neurosis when once a nervous irritation has been instituted. While immediate causes rarely induce long continued disorders, a pre-existing influence may serve to continue it indefinitely. It is of little practical importance that some exciting circumstance has given rise to a nervous trouble. The event has passed and cannot be recalled. If there is an underlying cause, it is of much more importance.

Persons in whom underlying causes of neurosis exist are said to possess a neuropathic predisposition, and those subject to it are liable from trifling immediate causes, to suffer from various neuroses. In a considerable proportion of cases the neuropathic tendency is hereditary. But the result is not always manifested in the same form in different generations.

A third class of cases which should be recognized may be designated as *modifying tendencies*, among which may be mentioned vitiated atmosphere, the period of life, and the performance of certain physiological functions.

Often as a result of the predisposing influence, when one form of complaint is supposed to be cured, the subject of it is simply suffering from some other form.

Must the predisposing cause of neurosis be general, pervading the whole organism, or must it of necessity be located in the great nerve centres, or may it be entirely local and outside those great centres? Undoubtedly it may be local, and confined to any portion of the nervous system.

Inasmuch as the tendency is often hereditary, may not the evil consist of some peculiarity of anatomical structure, or of physiological adaptations which are inconsistent with the most regular and easy performance of the function of a part or parts; and may not certain classes of mechanical peculiarities be unusually liable to become factors of physiological disturbance?

If we answer in the affirmative, we assume a hypothesis which must be maintained by long-continued observations conducted in a spirit of judicial independence, and free from the bias which might result from occasional and exceptional experiences. The conclusions announced this evening are based upon observations in more than five

thousand cases in private practice, and of a considerable number in public institutions, all of which have been made with as much precision as the exacting demands of an active professional life would permit. The central truth as arrived at by these observations may be stated as it has already been done in a memoir to the Royal Academy of Medicine of Belgium in 1883, as follows:

Difficulties attending the functions of accommodation and of adjusting the eyes in the act of vision, or irritations arising from the nerves involved in these processes, are among the most prolific sources of nervous disturbances, and more frequently than other conditions constitute a neuropathic tendency.

In the proposition, all causes of nervous irritation are recognized. It is held that the influences indicated are pre-eminent, but not exclusive permanent causes. Let it be remembered that it has been universally conceded that the nature of the neuropathic tendency is unknown. If one pre-eminently important element is demonstrated, it is not to be rejected because it may not include the whole.

The speaker proposed only to illustrate the result of his experience by exhibiting some photographs of cases of notable neuroses which showed very remarkable changes of physiognomy, such as habitually occurred when certain hurtful tensions of the ocular muscles were relieved. If he had designed to present only the most remarkable cases of the class to which these belonged, he would have chosen only a few of these. The design was, however, only to show by these contrasting photographs the very notable improvement which in obstinate and even by ordinary means hopeless cases of the most important neuroses might be expected, from relief from certain hurtful tensions of the eye muscles.

The portraits were in pairs, the first having been taken at the commencement of treatment, the second at a later period, the interval being on an average about one month. The first series represented cases in his private practice; the second series, cases which were under under his care for a short time at the Willard Asylum for the Insane last summer. The first series had been made by various photographers; the second by Dr. P. M. Wise, superintendent of the Willard Asylum. Thirteen pairs of photographs were exhibited, nine of the first and four of the second series. In all these very striking contrasts existed between the first and second portraits.

In No. 1, a weary and listless young girl, a sufferer from headache, and who had never been able to attend school, is seen to be transformed in twelve days to a vivacious and thoroughly awake child. Following relaxation of each of the inner eye muscles, the change in health was marvellous. In No. 2, an epileptic girl, whose vacant gaze and half-open mouth indicated a profound degree of dementia, within a single month put on an appearance of robust health and of lively intelligence. In another case, a boy, choreic from infancy and imbecile, whose constant movements were too rapid even for the modern photographer, showed in the second photograph, from which the distortions of the face and wrinkles in the skin had disappeared, a clever mental state.

The speaker related in brief some of the results of a short season among the most hopeless cases in the Willard Asylum for the Insane. Two of these hopeless cases, who had during the month preceding treatment directed to the eye muscles, been subjected to about one hundred and seventy convulsions, suffered only about forty convulsions in the month succeeding that treatment, notwithstanding the withdrawal of all bromides.

Fifty per cent. of epileptics so treated had remained well for a length of time varying from many years to only a single year, but sufficiently long to indicate that a great change had been wrought. Thirty-two per cent. had received very marked relief, but short of absolute cessation of the complaint. They were all better without drugs than they had formerly been with. In seventeen per cent. no good results had been obtained.

The speaker thought that with a better understanding on his own part of the extremely complicated conditions of the ocular muscles often found in epilepsy, this record could be improved.

The methods of procedure in examining for muscular defects was given. It differed radically from that proposed by Graefe and generally adopted, and from other methods which had been suggested. His method of performing tenotomy was also described.

In conclusion, Dr. Stevens said he thought it was not unreasonable to look for the future advance in medical practice along two great lines: the one related to micro-organisms, the other to irregular phenomena resulting from well-defined causes of irritation, which causes must be sought for principally in the direction of difficulties in the performance of necessary functions. With the removal of such difficulties we might look with confident expectation to the cessation

of the peculiar irregularity which constituted the special form of nervous disease.

Dr. E. C. Seguin said with regard to the ætiology of neuroses and serious mental disorders that he thought we ought to look a great deal deeper than the exciting and superficial causes which occurred in many cases of that kind. In epilepsy and chorea, for instance, he thought we had to look for the efficient cause not in disturbed external apparatus, but to hereditary predispositions and faulty tendencies. That faulty external apparatus would cause more attacks, or possibly aggravate the mental disorder, he thought no one would deny. Consequently, the optic apparatus, the genital apparatus, etc., should be put in perfect order. As to the great improvement after tenotomy in epilepsy, the records of surgery and medicine were filled with cases in which trauma of various kinds had interfered with epileptic manifestations for months, or even years. It seemed to him the report of a case within six months after tenotomy was rather premature. He referred to one of his cases of epilepsy recently submitted to division of the ocular muscles, the bromides at the same time being withdrawn, and three days later she commenced to have from six to twelve convulsions in the twenty-four hours—more than she had ever had before the operation. He had had patients go three years without an epileptic attack, and then have a relapse.

Dr. H. D. Noyes thought the precise ocular conditions in the cases reported should have been recorded; perhaps they were in that part of the paper not read. He had with him exact records of a number of cases of ocular trouble, with the result of treatment. It has not fallen within his experience to meet with the class of cases referred to by Dr. Stevens. He dwelt upon the importance of making a thorough ocular examination, including that of the muscles of the eye, in every case. He had come to realize more and more the importance of insufficiency of the external recti. He had obtained benefit in many cases from prisms. He spoke of the method of examination and of performing tenotomy. The paper deserved the most careful consideration.

Dr. D. B. St. John Roosa said that that part of the paper which especially concerned the ophthalmologist was as old as ophthalmology itself, and it did not call for discussion to-night. The real point in the paper was, he thought, that the correction of errors of refraction, improper relation between the ciliary and internal recti muscles, and other deviations of the ocular muscles, was capable of curing constitutional disease. He took it that epilepsy was a constitutional disease, and not merely a functional disturbance; the same was true of chorea. The question was, did these operations cure epilepsy and chorea? But it had been shown that people with chorea got well without ever having error of refraction corrected. It had also been shown that the vast majority of people who were not myopes were hypermetropics, yet suffered no inconvenience from it. In this, the author's second paper, another step had been taken, namely, that these constitutional diseases—epilepsy and chorea—were due not solely to errors of refraction, but to want of co-ordination between the recti and ciliary muscles. Then the prism test came upon the field, and we had to exercise the ocular muscles with prisms. Then in the order of advance came the doctrines taught in the paper to-night. Granting the claims of the paper, that the patients had for a time after correction of an ocular difficulty been greatly relieved, possibly cured, yet that was a long way from assuming that the ocular disturbance, whatever it was, was the cause of the epilepsy. Many great men having strabismus had not become choreic, epileptic, nor insane.

Dr. A. L. Ranney thought that following the exhibition of the photographs little need be said in confirmation of the views advanced by Dr. Stevens. The photographs were so startling that they would be accepted in any court of justice by an unprejudiced jury as proof that unmistakable benefits had been derived from the treatment. He had personally seen and examined several of the cases, and he considered the published histories as decidedly under-estimated. Dr. Ranney had performed the operation for the relief of ocular insufficiency nearly two hundred times, and had carefully examined the condition of refraction and accommodation, as well as that of the ocular muscles, in several hundred subjects afflicted with various forms of nervous dsiease. He did not pretend to pose as an oculist, but as a neurologist. Originally he was a skeptic, but his skepticism became no longer tenable when he saw a choreic and epileptic imbecile in Dr. Stevens's office who was perfectly restored in a short time to health and mental sanity by the method he had described. He thought the paper would tend to establish a new era in neurology. Regarding the operation, in no case had he had bad effects from it, but the treatment required careful regard to detail.

Respecting the view that the eye is an im-

portant factor in creating and prolonging the so-called "neuropathic predisposition," the following facts were pertinent:

1. No one has yet shown in what this predisposition lies, hence if Dr. Stevens has shown that eye-defect is an important element in these conditions, a great advance has been made.

2. There is no recognized pathology in functional nervous diseases.

3. Heredity is very common in these affections.

4. My records, in common with those of Dr. Stevens, go to show that eye-defect is found in a very large proportion of such subjects.

5. Many of the eye-defects found can be shown to be congenital—being inherited like feature.

6. The manifestations of the neuropathic predisposition vary with each case, and are called forth often by trivial circumstances which are too frequently regarded as of great clinical interest.

In the treatment of the severer forms of functional nervous disease—for example, in chronic epilepsy—one radical cure without the aid of drugs offsets a thousand failures as a proof of the scientific value of a discovery. Dr. Stevens had seven cases free from epileptic seizures for more than five years after tenotomy of the eye-muscles, and without the aid of drugs. This could not be explained by chance. Then the records of the Willard Asylum were hard to contradict.

During the past year and a half he had seen sixteen epileptics in private practice; in only one was no defect in the eye-muscles found. He had an opportunity to operate on the eyes in eight of the cases. Three of these were cured; two had had no fits for over one year. In the five cases still under observation the attacks had been lessened in all, drugs having been withdrawn. One had been reported by Dr. Stevens. In headache and neuralgia he had had some very remarkable results from tenotomy of the eye-muscles; also satisfactory results in hysteria and hystero-epilepsy.

Dr. Herman Knapp said his practice had not brought him much in contact with people who had neurotic conditions, and most of those whom he had seen had passed into other hands. He was very much surprised to learn that there was so high a percentage of ocular difficulties in the patients Dr. Stevens examined in the asylum. He thought nervous people generally showed not only one complaint. Many people, especially young ladies, who suffer from headache, etc., cease to complain after correction of a deviation of the eye-muscles, etc. He had listened with the greatest attention to Dr. Stevens, and he felt quite sure that his work was not only legitimate, but that it was highly promising. He was only afraid he would not be spared disappointments in that line of treatment.

Dr. Gruening said his experience had been very much like that of Dr. Knapp. He always examined for muscular defect, and said that when one placed a prism before the eye it disturbed binocular vision. For the correction of this apparent muscular defect an operation was performed, but the muscle was sewed to its original place, or the lateral attachment was not divided; and this was only the simulation of an operation. He hnd benefited many patients by cylinders.

Dr. Stevens, in closing the discussion, said there was no suggestion in the paper regarding cures. He did not believe in cures. Take away the cause of the trouble, and they get well. If the patients could not be said to be cured, it was still a very fortunate thing that they had got rid of their chorea, epilepsy, etc.

CHICAGO MEDICAL SOCIETY.

At the March meeting of this society several papers of general interest were presented. Of these the most noticeable was by Dr. A. E. Hoadley on

Deep Tubing of the Larynx as a Substitute for Intubation, with a Report of Nine Cases.

In these cases a tube was introduced so that the head of the tube rested within the larynx. Eight of the cases were able to drink consecutive swallows immediately after the operation. While all the cases were fatal, the deep intubation gave the greatest relief. Dr. Hoadley believed the most objectionable feature in the O'Dwyer method is the projection of the head of the tube over the top of the larynx, interfering with deglutition and exciting cough. This he proposes to obviate by "deep tubing," which he accomplishes by modifying the tube as follows: shortening the tube to nearly the length of the larynx, making the head of the tube conform more nearly to the interior of the upper part of the larynx, making the upper surface of the head of the tube cup shaped to facilitate the introduction of the extractor, having that portion of the posterior border of the tube corresponding to the arytenoid cartilages stand on

a plane anterior to that of the rest of the tube, so that pressure at this point will be slight, making the obturator three-eighths of an inch longer than the tube to facilitate the deep introduction of the tube. The long tubes, owing to the mobility of their lower ends, produce irritation in the trachea, exciting cough and pain.

EDITORIAL DEPARTMENT.

PERISCOPE.

A New Treatment of Gonorrhœa Chronica by Means of Grooved Bougies.

Dr. Leopold Casper thus writes in the *Lancet:*

The extraordinary difficulty of healing some cases of chronic gonorrhœa is well known. There are men who have every morning an exudation, although they have tried every possible remedy against the evil. Frequently, especially after coitus, the chronic disease becomes acute, which often, more particularly in young married men, leads to disagreeable results. The difficulty of healing chronic gonorrhœa is to be sought less in the means used than in the way in which they are used. This will appear when we more closely consider the anatomy of the urethra and chronic gonorrhœa.

The male urethra is a tube from fifteen to eighteen centimetres long, which in its separate parts is constructed so differently that it appears unjust *a priori* to place a disease of one of these parts under the class named "gonorrhœa chronica." For the same reason that the cervix uteri is to be separated from the uterus, the pars spongiosa must be separated from the partes membranacea and prostatica. An inflammation of the pars spongiosa does not necessarily imply that the pars membranacea is also inflamed, or, *vice versa*, that an inflammation has its seat in the membranous portion while the spongious part is normal. In fact, most cases of chronic gonorrhœa are located at the end of the bulbus, or at the juncture of the end of the bulbus to the pars membranacea. They begin as acute inflammation in the fossa navicularis and slowly extend to the bulbus. This will be clearly seen by the following: Of 100 cases of callous stricture, about seventy occur in the bulbus, or at the place where the bulbus becomes the pars membranacea, twenty in the fossa navicularis, and ten in other parts of the pars spongiosa. Never does a callous stricture appear in the pars prostatica. The callous stricture being the result of gonorrhœa, the favorite seat of this disease will of course be the above-mentioned places, where strictures mostly occur. Although, as regards the pars cavernosa, the abundance of cavernous tissue will favor hypertrophy of the stricture-producing tissue in a higher degree than in the partes membranacea and prostatica, still there would be more strictures in the posterior half of the pars membranacea and in the prostatic part, if all chronic gonorrhœa were to extend to the bladder. Of course the inflammation sometimes extends to the posterior part of the urethra, but this is not a rule. In this respect the acute and chronic gonorrhœa resemble each other. Rarely does the inflammation extend to the bladder in acute cases, whereas this frequently happens in chronic cases. Thus we speak of a "gonarrhœa anterior" when the inflammation does not pass the bulbus; if it extends further we call it "gonorrhœa anterior et posterior;" if the disease disappears before the bulbus and remains located in the posterior part of the urethra, we call it "gonorrhœa posterior." The bulbus is therefore a boundary in respect to the pathology of gonorrhœa. This will appear more comprehensible when we consider that the bulbus is also a boundary in an anatomical respect. The lamina media fasciæ perinei (Dittel), or the fascia perinei propria (Hyrtl), the important boundary between those organs which lie within the pelvis and those which lie outside of it, is closely connected with the bulbus. In front of this membrane is the pars cavernosa of the urethra, with the musculus transversus perinei superficialis and the musculi bulbo-ischio-cavernosi; behind it is the membranous and the prostatic portion, with the glandes Cowperi, the prostata, and the important musculus constrictor urethræ, also called "compressor partis membranaceæ urethræ." This muscle is composed of two bundles, of which the upper lies above and the lower under the pars membranacea; both join at the median line, together with the same muscles coming from the opposite side, so as to form a broad muscular ring to compress the urethra.

The importance of the bulbus as a bound-

ary of the anterior and posterior urethra is apparent when we consider the treatment of gonorrhœa as hitherto practiced—viz., injections by means of syringes. This method is suitable for most cases, but not for all; for the fluid injected into the urethra does not pass the bulbus without the use of force, which no one would care to employ. If an injection is made slowly, and with moderate pressure, the fluid extends to the front part of the urethra, and passes to the musculus compressor, but not beyond it; for, were this the case, the fluid would run through the posterior urethra into the bladder, and remain there, whereas it is known that after a common injection the fluid comes back on removing the finger from the meatus. The in-going solution causes a reflex action of the musculus compressor, which results in a spasmodic closing of the urethra. The inefficiency of the usual syringes for treating gonorrhœa chronica posterior is therefore clear. At the same time we must remember that, if we wish to irrigate the posterior portion of the urethra, we must not push the catheter so far that its point touches the bladder; for in this case the catheter fills the urethra, and the injected fluid flows out again through the eye of the catheter, without having touched the walls of the urethra.

Concluding from the foregoing that (1) all that which gathers before the musculus compressor in the urethra flows towards the orificum cutaneum, and that (2) a fluid gathered in the posterior part of the urethra runs into the bladder because of the inferiority of the musculus sphincter vesicæ internus as against the musculus compressor, we receive a hint as to the diagnosis between gonorrhœa anterior et posterior. If we see a drop on the orificum cutaneum, or that the lips stick together, or we find yellow spots in the washing, the gonorrhœa is surely seated at the bulbus, as all that which accumulates in front of the bulb flows toward the meatus. If these signs are absent, the diagnosis is more difficult. The passing of a button-ended bougie causes in most cases only a slight burning and discomfort to the sound portions of the urethra, but when we touch a sore part the patient feels severe pain. If there is tenesmus, we have surely to deal with a gonorrhœa posterior; if tenesmus is present, if a drop appears on the orificum cutaneum, if the lips are glued together, or there is a spot in the washing, a gonorrhœa anterior et posterior is proved. On the other hand, if there is no tenesmus, we are not justified in the conclusion that there is no gonorrhœa chronica posterior. In acute gonorrhœa posterior tenesmus always appears; in chronic we often miss it.

The examination by means of the endoscope is always decisive, but the irritation which even the most careful introduction of this instrument will cause renders its application undesirable. Less painful and much more simple is the following proceeding. Tell the patient to hold his urine for five or six hours, and then to pass it into two glasses.

If the first glass contains flakes or films, while the second glass remains clear, a gonorrhœa anterior may be diagnosed; should both glasses appear turbid, then a gonorrhœa posterior is present. To distinguish between gonorrhœa posterior and cystitis, which is likewise accompanied by turbid urine, is exceedingly easy; for, whereas in chronic posterior gonorrhœa the first portion of the urine passed is more turbid and contains more films than the second, in cystitis the reverse is the case. The reason of this is, that the pus formed in the bladder will, according to the law of gravitation, sink to the fundus vesicæ, and will therefore only appear in the urine expelled last.

Considering now the pathology of gonorrhœa, it is known that the inflammation, as differing from urethritis, does not remain in the mucous membrane. Beginning in the mucous membrane, it continues into the submucous tissue, in the corpora cavernosa, and in the muscles. The product of the inflammation is an infiltration of the cells of the diseased parts. This infiltration gradually becomes fibrous tissue (Bindegewebe), which in its turn produces the cicatrization called "stricture." At the same time epithelial cells are formed, reaching to the surface of the mucous membrane and forming a thick epithelial stratum. The upper cells of this stratum, constantly sloughing, exfoliating, and mingling with the mucous secretion of the glands, constitute the exudation which characterizes chronic gonorrhœa. The glands and lacunæ of the urethra are also affected. From the fossa navicularis to the bulbus there are many lucunæ Morgagni, from eight to twelve millimetres long and half a millimetre wide, and several Littré's glands. The catarrh extends to both glands, and Dittel considers the well-known flakes or films and the goutte militaire as a product of the catarrh of Littré's glands and of the sinus of Morgagni.

From this short review, it is clear that many chronic gonorrhœæ already represent the first stages of strictures, or, as Otis calls them, "large-sized strictures," which natur-

ally cannot be cured by astringent solutions, or even such as are fatal to gonococci. If they are to be cured, local pressure must be used to remove the cell infiltration, while medical treatment is adopted to affect the catarrh. For these reasons treatment with bougies against chronic gonorrhœa has been mostly practiced. Some went a step further and used bougies covered with simple salves; others, as Unna, employed bougies with a paste composed of butyrum cacao and different medicaments, which dissolve at body temperature. Similar considerations influenced me in the treatment of gonorrhœa chronica. But the usual bougies and the bougies covered with salves and paste not being successful in obstinate cases, I tried a modification. I was convinced that the paste bougies did not sufficiently fulfil their purpose, for very often the bougie does not reach the bladder, because the narrow walls of the urethra will not permit it to pass with the hardened paste; consequently one would have to wait, as Unna says, until the paste was dissolved, and then melted salves would not reach the places behind the stricture, where the catarrh is very often located, and for which they are intended. Further, cacao butter should not be allowed to enter the bladder if it can possibly be avoided, for after such treatment I have seen a simple gonorrhœa anterior become a gonorrhœa posterior and a cystitis colli with severe tenesmus; twice I have observed epididymitis after it, but I cannot decide whether *post hoc* or *propter hoc*.

These considerations caused me to devise a method which would have the advantages of the combined mechanical and chemical treatment, and at the same time avoid the evils I have mentioned. For this purpose I avoided nickel-plated bougies with grooves. These bougies are slightly conical and twenty-five centimetres in length. They have six grooves, which are about a millimetre and a half deep, and become shallower towards the point, stopping entirely at about five centimetres from the point, so that the front part of the bougie is entirely smooth.* Into the grooves of these bougies I pour a paste, which hardens at the ordinary air temperature. With respect to the composition of the paste, I recommend the following: Cacao butter, 100 parts; nitrate of silver, 1 to 1·5 part;† balsam of copaiba, 2 parts. I tried, also, other preparations, such as resorcin, iodoform, zinc, and iodnatrium, but found them all inferior to the nitrate of silver. With regard to the preparation of the bougies, I must lay stress on the fact that the salve must not be heated too much, for in that case the nitrate of silver would be reduced to silver and would be inefficient; therefore, put about two teaspoonfuls of the paste into a small vessel and heat it slowly and carefully. The vessel must not become so warm that it cannot be touched with the bare hand. Such a degree of heat is not necessary to dissolve the paste, and, as I have shown, is injurious. Neither is it necessary to wait until the entire contents of the vessel are melted, for if so the already dissolved salve becomes too hot and reduced. After dissolving, the salve is poured over the bougie, which is horizontally laid over a vessel to catch the drippings. After the salve has become hardened the bougie is smoothed with any sharp-edged tool. Care must be taken that the smooth front part of the bougie is left uncovered by the salve. Before using, draw the bougie several times through the hand, the warmth of which will cause sufficient of the salve to melt to lubricate the metallic surface of the bougie. The smooth front part of the bougie is rubbed with glycerine so that the instrument, if the size corresponds to the diameter of the urethra, will easily pass. The grooved bougie leads the salve beyond the narrowed places. At the temperature of the body the salve melts in one minute.

The greater efficiency of medicaments in this form over injections is clear, as the oily cacao butter will keep the ingredients in closer and longer contact than water. As to the glands and laminæ of the urethra, it is probable that the thick fluid matter enters them more easily after they have been dilated by the bougie. Of the bougies described, I use Nos. 18 to 23, French (Charrière). I never use smaller than No. 18, but prepare the urethra with small bougies until this size will pass. As soon as this is accomplished, I begin the cure with my grooved bougies, which I pass daily. If there is difficulty in passing No. 18, I employ the same sized bougie the next day, and then pass on to No. 19, etc.

After using these bougies. I have never witnessed a case of chill or fever, but I will not say that this could not occur just as after passing ordinary bougies. The pain or disagreeable feeling is not greater than that caused by the introduction of any other instrument into the urethra. Nay, the well-known burning in the urethra frequently

* Weiss & Son, of 287 Oxford street, London, manufacture these bougies, for which an English patent has been applied for.

† Old-standing cases require more than one part of nitrate of silver, but I should not recommend more than 1·5.

experienced by patients in passing urine after the first application of the bougie will often be entirely absent. The longer the bougie is left in, the more favorable is the effect on the infiltration. Some patients feel burning and tenesmus after a few minutes, others after half an hour, and others still later. The time during which the bougie may remain in is dependent on these circumstances. Although the salve is so prepared that it cannot injure the normal parts, I avoid introducing it unnecessarily into the posterior portion of the urethra, whence it would flow into the bladder. I effect this by passing the bougie, in a case of gonorrhœa anterior, only so far that its point just touches the musculus sphincter vesicæ internus. As the grooves with the salve begin at a distance of five centimetres from the point, none or very little salve will flow into the posterior urethra. In a case of gonorrhœa posterior I push the bougie further, so that its grooved part lies in the partes membranacea and prostatica. Here we cannot avoid a little of the salve flowing into the bladder. The results I have obtained with this treatment are satisfactory. On an average, I succeeded by ten applications to effect a cure of cases of chronic gonorrhœa which had before proved very obstinate. In a few cases twenty and more applications were necessary Frequently after using a very small number of bougies a striking improvement was visible.

Whether a chronic gonorrhœa which no longer shows a secretion at the meatus will improve can be decided by simply examining the urine with the naked eye. The quantity of gonorrhœal flakes, their size and length, will diminish with the gradual process of cure. The microscope teaches us at the beginning the thick flakes are almost entirely composed of pus-corpuscles, while epithelial cells are but few. With the improvement of the chronic gonorrhœa the quantity of pus-corpuscles diminishes, and that of epithelial cells increases, till at last but few pus-corpuscles are to be found here and there embedded in the epithelial cells. Thus we are enabled exactly to observe the different stages of chronic gonorrhœa. More than once I could readily, after two applications, perceive a difference in the composition of the flakes in so far as the proportion of epithelial cells to pus-corpuscles had changed in favor of the former. Altogether by this procedure I have cured about fifty obstinate cases of chronic gonorrhœa, which had resisted all other methods; twenty-seven of these had been cases of a year and a half's standing, twelve of more than a year's standing, and others less.

On the Treatment of Sneezing, Hay-Fever, Asthma, etc., by the Galvano-Cautery.

Dr. F. De Havilland Hall thus writes in the *Lancet*, November 13:

All introducers of novel medical or surgical procedures are apt to run to extreme lengths, and to arrogate to the plans they have brought forward claims to which they can have no pretension; hence the caution with which the statements of innovators must be received. It would be a great pity, however, if these extravagant assertions should prevent attention being paid to the kernel of truth contained in the husk of excessive laudation; and this seems especially needful in regard to the views propounded by Hack, of Freiburg, who undertook to cure a large number of neurotic affections by the free use of the galvano-cautery to the mucous membrane covering the inferior turbinated bone; later on, he certainly modified his opinion somewhat, but he still claims too large a field for this plan of treatment. That there are certain neurotic affections the starting-point of which is the nasal mucous membrane cannot, I think, be denied, and in these cases cure can be most readily effected by treatment directed to the part primarily affected. Hack, by pointing out that the most ready method of influencing the nutrition of the mucous membrane of the nose is by the employment of the galvano-cautery, has enabled us to treat successfully and promptly many cases formerly very difficult to manage. As a type of the kind of case in which I would use the galvano-cautery to the nose, the following may be taken as a good example.

Mrs. C., aged twenty-seven, was sent to me last May by my friend Dr. Penny, and she gave the following account of herself. She said that she had been married eighteen months. In June, 1885, while pregnant, she commenced to suffer from violent fits of sneezing; these continued to occur very frequently until October 25, when she was delivered of a still-born child, the limbs of which were said to be much contorted. On inquiry I found that for the last three or four years she had suffered from hay fever, usually lasting about a month. When she applied to me in May, she stated that she was again pregnant, being rather more than three months advanced; that the fits of sneezing had recurred as severely as last year, and that her doctor had advised her that it was of the utmost importance, in

view of what had occurred in her former pregnancy, that she should seek relief from her distressing ailment. Apart from the sneezing, her general health was good in every respect. I found the mucous membrane covering the inferior turbinated bone on the right side greatly hypertrophied; the same condition, though somewhat less marked, existed on the left side. After applying a solution of cocaine, I used the galvano cautery (as described later on) to both nostrils. The patient did not complain of any pain from the procedure. She was directed to come again in a fortnight. As I was unfortunately prevented by illness from seeing her, Dr. Butlin kindly made the second application of the galvano-cautery. I next saw her on July 3. She informed me that the sneezing was not so bad as formerly; it was less frequent at night, and there were only about four attacks daily. On examining the nose, the mucous membrane was found to have contracted to such an extent that I did not think it necessary to make another application of the galvano-cautery. I recommended her to use a 2 per cent. solution of cocaine in the form of spray night and morning, and to have a bottle of carbolized smelling-salts to inhale whenever an attack of sneezing seemed imminent. The further history of the patient is best told in an extract from a letter I received from her husband on August 17: "I am very pleased to be able to report *very great* improvement; I cannot say that it has quite left her, but it is only very occasional now, and nothing like it used to be. The carbolized salts prevented many an attack of sneezing, and she is able to do without the spray, and I think it may now be said that she is cured of a most inconvenient and, in her case, dangerous complaint."

When I undertook the treatment of this case I was not very sanguine as to success. In the first place, I do not think that the condition of the nervous and vascular system which obtains in pregnancy is likely to influence favorably a procedure, the object of which is to remove the tendency towards certain reflex actions by diminishing or annihilating the irritability of the locality upon which the train of symptoms depends. Secondly, it was to my mind very uncertain to what extent the fœtus in utero was itself the predisposing cause of the attacks. In favor of this view was the fact that after delivery the attacks ceased, only to recommence when she became pregnant. Lastly, there was the history of several attacks of hay fever, and I was afraid that though she might get temporary relief, nevertheless during the summer months she would probably have a return of the complaint. The result, however, was better than I expected.

The introduction of cocaine has inaugurated a new era in the treatment of nasal diseases and of the various reflex symptoms dependent thereon. This has been brought about in two ways: first, and most important, the local anæsthetic effect of cocaine enables one to perform most operations within the nose without causing the patient pain worth speaking of, and without having recourse to general anæsthesia; and, secondly, by the power it has of causing contraction of the nasal mucous membrane, a much better view can be obtained of the posterior nares. The method of treatment I employ is the following: In the first place, it is necessary to make an examination of the nasal mucous membrane without the use of cocaine; otherwise, owing to the action of the drug to which I have just alluded, the hypertrophied parts might be overlooked. Having settled which areas are to be attacked, I spray out the nostril with a 10 per cent. solution of cocaine. Then I wait five minutes, and apply, by means of the brush, a 20 per cent. solution of the same drug to the part of the mucous membrane which is to be cauterized. Again waiting five minutes, I try if the sensibility of the mucous membrane is annihilated; if not, I wait a little longer, or, if necessary, make a second application with the brush. As soon as I have satisfied myself that the mucous membrane is insensible to pain, I make two or three deep furrows parallel to one another in the mucous membrane by means of one of Schech's delicate platinum-headed galvano-cautery instruments heated to a red heat by a galvanic battery. All that the patient will have to do after the operation is to pass a little cold cream or zinc ointment up the nose, which will relieve the smarting caused by the burning. In about a week or ten days, according to the depth of the furrows and the idiosyncrasy of the patient, the burns will have healed, and, if necessary, a further application may be made, though I prefer to wait two or three weeks to see how much contraction has taken place before repeating the process. If the cocaine has been properly applied, there is little or no pain at the time of the operation, and though occasionally the patients complain of the smarting which comes on the next day, some cooling application generally suffices to relieve this.

Notwithstanding that I have a firm belief in the efficacy of this operation—if so sim-

ple a procedure may be dignified by the name—I do not usually employ it till I have tried other measures and failed. I remember one case in particular which I saw three years ago. In this patient there was hypertrophy of the mucous membrane of the nose, with the history of violent attacks of sneezing and running from the nose; after a time the sneezing ceased, and was replaced by attacks of asthma, coming on about 1 a. m. and lasting till 4. I had quite made up my mind to operate, but, as the patient was pregnant, I thought it advisable to wait until after her confinement, so I ordered her a mixture containing three grains of citrate of caffeine and ten grains of bromide of potassium. I did not see the patient again for some months, but on her next visit she told me that she had experienced great relief from the mixture, and that she had not had a bad attack of asthma since her last visit. I have seen her again within the last few months, but, as her condition has much improved, I do not think it will be necessary to have recourse to the galvano-cautery. In Vol. I. of the Westminster Hospital Reports, I have recorded a case of excessive sneezing which had lasted for eleven months; in this patient, syringing out the nostrils with a luke-warm solution containing the glycerine of carbolic acid, borax, and the bicarbonate of soda, sufficed to effect a speedy cure. I have mentioned these two cases to show that it is not necessary in all attacks of violent and protracted sneezing, hay fever, asthma, etc., to employ the galvano-cautery, though in some cases the cautery is the most speedy and certain method of treatment.

Before ending this short account, I would wish to direct attention to the carbolized smelling-salts, from which the patient on whose case this communication is based derived much benefit. I have ordered the salts very frequently, and they almost invariably give relief; and to persons prone to coryza I would strongly recommend them. Directly the usual indications of a cold in the head are experienced, the salts should be inhaled, and recourse had to them every ten or fifteen minutes while the irritation about the nose lasts. In my own case I have aborted many a threatened attack of coryza by this means. As regards the use of cocaine spray for the relief of hay asthma, I do not think much good is to be expected from this drug; the constringing action which at first results from its use is followed by a dilatation of the vessels, and the fluxion which accompanies this sometimes sets free the reflex, which results in an attack of sneezing or asthma.

The Dietetics of Pulmonary Phthisis.

Dr. A. L. Loomis formulates the following rules to govern the dietetics of phthisical subjects (*Journal of Reconstructives*, October, 1886):

1. Every phthisical patient should take food not less than six times in the twenty-four hours. The three full meals may be at intervals of six hours, with light lunches between.

2. No more food should be taken at any one time than can be digested easily and fully in the time allowed.

3. Food should never be taken when the patient is suffering from bodily fatigue, mental worry, or nervous excitement. For this reason, mid-day naps should be taken before, not after, eating. Twenty to thirty minutes' rest in the recumbent posture, even if sleep is not obtained, will often prove of more value as an adjuvant to digestion than pharmaceutical preparations.

4. So far as possible, each meal should consist of such articles as require about the same time for digestion, or, better still, of a single article.

5. Within reasonable limits the articles of any one meal should be such as are digested in either the stomach or intestine alone, *i. e.*, the fats, starches, and sugars should not be mixed with the albuminoids, and the meals should alternate in this respect.

6. In the earlier stages the amount of fluid taken with the meals should be small, and later, the use of some solid food is to be continued as long as possible.

7. When the pressure of food in the stomach excites cough, or when paroxysms of coughing have induced vomiting, and the ingestion of food must be delayed until the cough ceases, or an appropriate sedative may be employed. In those extreme cases where every attempt at eating excites nausea, vomiting, and spasmodic cough, excellent results are attained by artifical feeding through the soft-rubber stomach-tube.

8. So long as the strength will permit assimilation and excretion must be stimulated by systematic exercise, and when this is no longer possible, the nutritive processes may be materially assisted by passive exercise at regular intervals.

The following may serve as a sample menu for a day in the earlier stage. The meat soup is made by digesting finely chopped beef (1 ℔.) in water (Oj.) and hydrochloric acid (♏ 5) and straining through cheese-cloth. Menu:

On waking, one-half pint equal parts hot

milk and Vichy, taken at intervals through half an hour.

8 a. m. Oatmeal with abundance of cream, little sugar; rare steak or loin chops with fat, cream potatoes; soft-boiled eggs, cream toast; small cup of coffee, two glasses of milk.

9 a. m. Half ounce cod-liver oil, or one ounce peptonized cod-liver oil and milk.

10 a. m. Half pint raw meat soup; thin slice stale bread.

11–12. Sleep.

12:30 p. m. Some white fish; very little rice; broiled or stewed chicken; cauliflower; stale bread and plenty of butter; baked apples and cream; milk, kumyss, or Matzoon, two glasses.

2 p. m. Half ounce cod-liver oil, or one ounce peptonized cod-liver oil and milk.

4 p. m. Bottle kumyss or Matzoon; raw scraped beef-sandwich.

5:30–6 p. m. Rest or sleep.

6 p. m. Some thick meat or fish soup; rare roast beef or mutton; spinach; slice stale bread; custard pudding; ice cream.

8 p. m. Half ounce cod-liver oil, or one ounce peptonized cod-liver oil and and milk.

9–10 p. m. Pint iced milk; cup meat soup.

1–2 a. m. Glass milk, if awake.

An Experimental Research upon Rabies.

Dr. Harold C. Ernst, having received two rabbits which had been inoculated in Pasteur's laboratory, undertook to prove experimentally the following propositions:

1. Is there a specific virus in the brains and cords of rabbits inoculated with Pasteur's material and after his methods?

2. Does the treatment by drying, proposed by him, modify the strength of this virus? And, finally,

3. Does injection with such "modified virus" produced an immunity against an inoculation (or bite) with virus of full strength?

His results with the experiments in detail appear in the April number of *The American Journal of the Medical Sciences.* Dr. Ernst began the investigation as a skeptic, but his experiments seem to justify a change from skepticism to a belief in, at least, a portion of Pasteur's assertions.

The conclusions which Ernst draws from his experimental work he summarizes as follows:

1. There exists in the cords and brains of animals inoculated in Pasteur's laboratory *a specific virus,* capable of the production of similar symptoms through a long series of animals.

2. That these symptoms are produced with absolute certainty when the method of inoculation is by trephining the skull, and injection under the dura mater, with less certainty when the inoculation is by subcutaneous injection.

3. That the strength of this virus is lessened when the cords containing it are removed from the animals and placed in a dry atmosphere at an even temperature.

4. That the symptoms produced by the inoculation of this virus only appear after a certain period of incubation, distinctly shorter when the inoculation has been done by trephining, than when done by subcutaneous injection.

5. That injections of the virus, modified in strength by drying, and in the manner prescribed by Pasteur, exert a very marked protective influence against an inoculation with virus of full strength.

6. That a very moderate degree of heat destroys the power of the virus entirely, whilst prolonged freezing does not injure it.

As will be seen, all of these conclusions are in complete accord with the declarations of Pasteur; their importance lies in the fact that they were reached at a distance from him, and by work entirely separated from any personal influence or bias.

The Means of Topographical Diagnosis of Focal Disease Affecting the So-called Motor Region of the Cerebral Cortex.

The necessity for exact knowledge of the relations between the external surface of the head and the various encephalic regions has arisen so rapidly within the last few years as to force each practical surgeon to work out the required facts for himself with the aid of the few papers that have appeared on the subject. Owing to the absence of any comprehensive monograph giving a complete directory, as it were, of those parts of the brain whose function is so far understood as to admit of the localization of lesions within their boundaries, Mr. Victor Horsley has presented in the April number of *The American Journal of the Medical Sciences,* for the use of those who may be called upon to explore the cranial cavity, a summary of the means adopted by himself as topographical guides to definite portions of the brain, which have so far, in his experience, fortunately been equal to the exigencies of ten cases submitted to operation.

The localization of disease of the encepha-

lon is obviously a two-sided process. First, the diagnosis of the seat of the disease in the nerve tissue, by observation of the symptomatic perversion of function; and, secondly, the determination of the particular part of the skull and soft parts covering the focus of disease. The second part of the process has usually been separated from the first, and considered by itself, under the title of cerebral topography, and may, doubtless, with advantage be thus studied as a distinct subject; but it really is in closer connection with the other division, namely, cerebral localization, than may appear at first sight to the anatomist.

Mr. Horsley points out that the localities in which different functions are represented are not separated by hard outlines (and this belief is also borne out by experiment), but that they occupy absolutely constant focal positions, and in this way will in the immediate future be very accurately mapped out.

The topographical relations of the so-called motor region to the exterior of the skull are lucidly explained, and then he presents an enumeration and limitation of the areas of representation of the different parts of the body in the gyri thus topographically determined. The text is fully elucidated by numerous diagrams.

Pilocarpine in Rheumatismal Tetanus.

The *Pester Med. Chir. Presse*, No. 11, publishes notes of a case of rheumatismal tetanus cured by pilocarpine. A peasant woman, 40 years of age, complained of difficulty in swallowing, which had troubled her for several days. She was unable to open her jaws more than 4 millimetres wide. Dr. Brunäuer (of Eslau) remarked that the muscles of the jaws, of the thorax, and of the abdomen were painfully contracted; the teeth were pressed together so tightly that the patient could not put out her tongue. During the night the attacks were not so frequent (from six to eight); there was a slight relaxation of the masticatory muscles, but the jaws could not be opened more than 2 or 3 millimetres wide; the contractions of the thorax and of the abdomen were clonic, and only became tetanic accidentally; the patient complained of suffocation. T. M., 38; T. V. 38.5; P. 110. The patient could not account for her disorder. The smallest excitement, a draught, a sudden exclamation, etc., caused the contractions. Subcutaneous injections of morphine were practiced during five days. Bromated and iodated preparations, preparations of zinc, salicylic acid, quinine administered internally and in injections, gave no relief. Dr. Brunäuer practiced injections of pilocarpine in doses of 2 centigrammes a day; violent perspiration was induced and prolonged for six or eight days. During the night hydrate of chloral was administered. At the end of nine days' treatment, the patient took 18 centigrammes of pilocarpine; the convulsions completely disappeared, and the patient was able to open her mouth.

Cataract Induced by the Vibrations of Tuning-forks.

Dr. S. Th. Stein, in order to examine the functions of the cochlea, acted on the eyes of very young porpoises, both in the unmutilated state and after the ears had been destroyed, by means of the vibrations of tuning-forks of different pitches. Cataract was produced in both classes of experiments. In the entire animals continuous subjection to the action of a high-pitched tuning-fork induced cataract in from eighteen to twenty-four hours, while a tuning-fork vibrating 100 to the minute produced the same effect in twelve hours. In animals whose ears were destroyed the cataract was much more quickly induced by the tuning-fork, some two or three hours being then sufficient. Dr. Stein's theory is that the condition of the lens is affected by the giving off of heat from the body, and that this is altered by the vibrations, the perception of sound again tending to retard the development of cataract. The members of the Moscow Medical Congress, before whom Dr. Stein related his experiments, did not appear inclined to accept his theories; and Professor Khodin remarked that it was not an uncommon thing for young porpoises to be born with cataract. To this, however, Dr. Stein replied that the cataract produced by his tuning-forks passed off after a time, and could then be re-induced by the same method.

Midwives in Finland.

The obligatory course of studies for midwives in Finland is of one year's duration. There is a supplementary course of two weeks, for those who have shown unusual aptitude, in obstetrical operations, such as embryotomy, the use of the forceps, etc. The students are almost all women of the lower classes, and the only requirements are that they shall be able to read and write. They are allowed to perform operations only when it is impossible to procure the services of a physician.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

HOW CAN THE PRESENCE OF SINGLE TUBERCLE-BACILLI BE DEMONSTRATED?

Though there still may be some authors denying the pathogenic character of micro-organisms, all agree that the presence of the so-called tubercle-bacilli in the sputa of persons suffering from cough and expectoration, proves beyond the shadow of a doubt, the existence of a tubercular diathesis, while on the other hand the absence of these microbes is by no means a sure indication of the non-tubercular character of the lung disease, as in certain stages of the tubercular malady and under certain conditions these bacteria do not appear in the sputa. It surely is of grave importance as regards regards diagnosis and treatment, as well as regards prognosis, to be able to decide early in such a complaint the tubercular or non-tubercular nature of the ailment. Physical exploration in the earliest stages often leaves us in the dark, and the demonstration of the presence of tubercle-bacilli in the sputum, if possible, is therefore of great importance. There is ne longer any difficulty in discovering large quantities of these microbes, and the MED. AND SURG. REPORTER has at various times informed its readers of the best methods to be pursued in these investigations. The difficulty heretofore existing when the presence of but a few of these bacteria had to be discovered, has now happily been removed, thanks to the exertions of Dr. Biedert, who, in the *Berl. Klin. Woch.*, 12–13, 1887, describes a procedure calculated to prove the presence of single tubercle-bacilli in the sputa.

B. conceived the first idea of his procedure from the fact that in tuberculous pus the bacilli collect at the bottom as time wears on. Though they are first intimately mixed with the sputum, slowly but surely they sink to the bottom. His method is as follows:

A tablespoonful of the expectorated matter is boiled with two tablespoonsful of water and fifteen drops of liquor sod. caust. until the whole has become a uniform fluid with no viscidity whatever remaining; then four tablespoonfuls of water more are added, and the boiling is continued until a uniform fluid is obtained, in which only here and there some minute particles swim. Then the mass is allowed to cool, and should then the whole not remain a thin uniform fluid, not coagulating, and with no viscid character, from three to six more tablespoonsful of water may be added to it. The mass resulting is preserved in a glass wider at the top than at the bottom, but after 48 hours the fluid on top is poured off until there re-

mains a layer from five to eight mm. high. From this a few drops are removed by the aid of the (first brought to a white heat) platina-spoon, care being taken to bring with them some of the minute particles swimming in the fluid, and the whole is transferred to the slide, dried, and colored.

In this manner, even should in the original sputum but a few bacilli have been present, one will find in the new preparation a great many of them; but to clearly demonstrate their presence it is necessary, on account of the addition of the caustic soda, to employ the Neelsen-Johnes method for the purpose of coloring. The latter consists in leaving the suspected sputum for one hour in a 5 per cent. solution of carbolfuchins, then the color is removed with 25 per cent. sulphuric acid and the recoloring done with malachite green.

B.'s method saves the trouble with numerous slides, and enables us to demonstrate the presence of tubercle-bacilli in the sputum, even when only one or two bacteria are contained in the latter. In conclusion, B. quotes two cases, where after a chronic consolidation of a portion of the lung had been in existence for some time, a tubercular deposit occurred later and led to tubercular phthisis, the examination of the sputa alone having indicated the grave change.

DR. SQUIBB ON MEDICAL ADVERTISING.

Dr. E. R. Squibb, of Brooklyn, N. Y., is a manufacturer of medical supplies, and publishes a small periodical called *The Ephemeris*, for the purpose of discussing and advertising them. He does not advertise himself in other medical journals, having one of his own; and this manner of doing business no doubt pays him, and he is not open to criticism for adopting it.

But when he goes out of his way to indulge in covert sneers at the advertisers in the medical press generally, and publishes half-disguised expressions of contempt for all physicians who read these advertisements and are induced to buy goods of somebody besides Squibb—then he does deserve criticism, and that in severe terms.

To justify these remarks, we quote the following from the January number of the *Ephemeris*:

"There are a large number of physicians who, for both therapeutics and materia medica, depend largely—if not mainly—upon the traveling salesmen and their pamphlets and lists, and on the advertising pages of the medical journals. The relations of this class to their supplies is most simple and most favorable. They come in very direct and very close contact with the sources of their supplies, and have much less trouble than any other class of artisans. *With others smarter, more ingenious, and more pl'n ible than they, to think for them*, and then to apply vigorous mercantile principles to their wants thus suggested for them, *they have the least practicable amount of thinking for themselves to do*, in regard to their remedies and the novelties of the day, and therefore, as they argue, more time to think of and study out their cases. To this class the ready-made prescriptions in the form of beautifully colored and coated pills, or palatable solutions and mixtures, do not appeal simply as gratifying various degrees of laziness, or indisposition to think for themselves, but they present themselves as true labor-saving devices, skilfully prepared for the over-worked ability to use them, and as giving more time for the higher and more scientific reaches of the profession."

The words we have italicised are as deliberate an insult to the intelligence of the profession of the United States as we remember to have read. They are false in spirit and in letter, and for Dr. Squibb, who has amassed his large fortune by the favor of his profession, thus to turn upon it, is not creditable to him in his latter years.

Is he losing the market for his products, that he turns thus bitter? Does he forget that to travel about to medical society meetings and read papers about the drugs he has for sale is just as much advertising as to take a page in the *Record* or the REPORTER? Dr. Squibb has received a great deal of gratuitous advertising in medical journals; he has been smart enough to get to windward of a good many medical editors; let him not display ingratitude for what the medical press and the medical profession have done for him.

NOTES AND COMMENTS.

Waking Numbness.

Dr. Andrew H. Smith, in the April number of *The American Journal of the Medical Sciences*, describes, under this title, a heretofore undescribed neurosis, and reports four cases—from a study of which it appears that the numbness is something added to the normal condition. It is a purely subjective condition. There is no paralysis of motion or sensation, the tactile sense is unimpaired, there is no change in the temperature of the affected part, the surface is not blanched or mottled, there is no tenderness on pressure. These characteristics separate this condition widely from those known under the names of night-palsy, local asphyxia, digiti mortui, Raynaud's disease, erythromelalgia, and from the various paræsthesias and acroneuroses heretofore described.

Doubtless the conditions upon which the numbness depends are present during sleep, but the sensation is not sufficiently strong to arouse the sleeper, and he first becomes conscious of it when awakened by some other cause.

The cause of this condition is probably central, since the effect is usually symmetrical. It would seem to be connected with the lowering of the circulation which takes place during sleep, and to disappear when the circulation returns to the waking condition, whether the return be spontaneous, or the result of rubbing, etc. As to the latter, it is doubtful whether it has any other effect than that upon the general circulation which the muscular exertion would necessarily produce.

As for treatment, in the only case in which the condition existed by itself, and independently of more serious conditions, ergot, digitalis, strychnia, and aconite, were tried at different times, but without result. The inconvenience produced by the affection was so slight that no treatment was carried out efficiently, so that even these negative results were of no value. In each of the other cases there was a diseased condition present, to which the numbness was subordinate, and which afforded the indications for treatment. In proportion as the treatment of the underlying condition was successful, the numbness disappeared. If it be true that the cause is central, no local treatment is likely to be of service.

Inoculation as a Preventive of Yellow Fever.

Dr. Bustamente, of Cucuta, Colombia, says of this subject:

"Dr. Urricoechea, surgeon of the frontier battalion, inoculated, by way of experiment, and with good results, five of his soldiers. Twenty minutes after the operation the temperature gradually ascended to 40° C., accompanied with all the symptoms of yellow fever. This lasted forty hours, at the expiration of which had disappeared the fever and all attendant symptoms. This operation was effected in a place called Moras, three leagues from Cucuta, and where a body of troops were stationed, who have not come to this city for fear of the fever. At present the inoculated soldiers are here, exposed to the action of the focus of infection. As in Moras, no case of the epidemic has as yet presented itself." Dr. Bustamente, in his letter, states that "as my labors in the field of inoculation as a preventive of yellow fever are only, it may be said, mere experiments, which, although they may satisfy me with a well-founded hope of successful and complete result, cannot be of genuine utility until the best and most efficacious method is decided upon. I am thinking, however, of making an abstract of my observations, together with the method pursued, the results obtained, and everything that may be useful in the premises. For the present I will confine myself to the statement that in more than forty persons whom I have inoculated, a fever, with many of the characteristic symptoms of yellow fever, has presented itself; this fever, developed by inoculation, varying several tenths of a degree, and in some cases ascending to 41° C., but never presenting the most grave symptoms of yellow fever. The result of my observations permits me to state positively that the fever produced by inoculation is attended with no danger, and it is safe to inoculate, as I have already done, from children of two years of age to the oldest individuals. Many of the persons inoculated have come to this city, and in no case has the yellow fever attacked them, which gives me hope of a final result completely satisfactory. The municipality, assisted by the merchants, sent to Mexico, January 10, a commission composed of two physicians, in order to study the inoculation of the fever."

Intussusception Produced by the Presence of a Tumor Growing from the Mucous Membrane of the Transverse Colon.

Mr. Arbuthnot Lane described this before an English Medical Society. After an attack of diarrhœa, in a chronic case of hip-joint disease in a child æt. eight, a tumor as large as a walnut was found projecting from the anus. It was much congested, blood oozed from its surface. The nurse in attendance supposed it to be a prolapse of the mucous membrane of the rectum, and attempted to return it within the anus, but was unsuccessful. On examination, the tumor appeared to have a very long pedicle, which gradually increased in thickness, extending beyond the reach of the finger. As there were no symptoms of strangulation and as the length of the pedicle was doubtful, he returned the tumor within the rectum. It soon passed out of reach. On the following day the tumor could be felt in the middle line, between the umbilicus and symphysis, between the finger in the rectum and the hand on the surface of the abdomen. Some days after, during another attack of diarrhœa, the tumor was again extruded from the anus. On this occasion it was found that the tumor was

sessile, and that it was attached to the very congested mucous membrane by a constricted neck, the prolapse of gut being abundant and lax, so that on the first occasion the whole of the thin apparent pedicle must have been formed by mucous membrane and the intestine itself. On the removal of the tumor, the prolapsed gut was readily replaced above the pelvic brim by the finger, and examination on subsequent occasions showed no signs of an intussusception. No tumor could be felt in the abdomen on either occasion in which the growth projected from the anus.

Congenital Occlusion of the Pharynx.

A Spanish practitioner, Don M. D. Illera, gives in *El Siglo Médico* an account of a case in which a newly-born child could not be taught to suck, and whose mouth on the introduction of the finger grasped it like a ring. On inspection, the middle third and edges of the tongue were found to be connected to the superior alveoli by firm adhesions, which entirely prevented the organ from being depressed. In addition to these adhesions, two little tumors were seen on the palate near the arch of the fauces, which almost occluded the passage into the pharynx, thus rendering swallowing of liquids almost impossible. It was evident, therefore, that unless operative measures were resorted to, the child must necessarily succumb very shortly from sheer inanition. The parents, however, though the state of the case was laid before them, refused to permit of an operation till the fourth or fifth day, when they decided to allow it. Don Illera seized the tumors with forceps, and cut them off at the base, touching the bleeding surface immediately with the actual cautery. The adhesions were then divided, and after the application of a sponge with cold water for a few hours, repeated very frequently, the child was able to swallow some milk quite easily, and ultimately attained complete use of the tongue. Don Illera was induced to publish the case, as he once saw a similar case in which the practitioner in attendance had considered the risk of operation too great to be attempted.

Inherited Congenital Deformity of the Hands and Feet.

Before the Clinical Society of London, Dr. H. B. Robinson read notes of a case in which a plastic operation had been done on the feet. The patient was a child, æt. 3½. The two inner toes were coalesced into a single great toe. and the three outer toes were similarly united into a little toe; the coalescence extended in part into the metatarsal bones, and there was a wide and deep cleft between. The operation consisted in removing the skin from the contiguous parts of the cleft, and then uniting the edges after the toes had been pressed together. A more shapely and more sightly foot was thus obtained. The child was one of several who suffered from a similar deformity, and her mother, herself affected, feeling the inconvenience of such a foot, had taken her to the hospital to see whether something could not be done to remedy the defect. The author showed a family tree, from which it could be seen that the deformity affected three generations. The first to suffer was the child's grandmother, and of thirty-six lineal descendants sixteen were malformed. The malformation was perpetuated through the female branches of the family. It was singularly uniform in its manifestations, and was attributed originally to a fright. The patient and several members of her family were exhibited.

Brachial Monoplegia Complicating Enteric Fever.

A male, æt. 22, came under the observation of Dr. Archer (*Med. Press*) at the beginning of the second week of enteric fever. The case was a severe one, and was marked by absence of diarrhœa; there was also delirium and picking at bedclothes, and occasional profuse sweatings. On the fifteenth day numbness was first noticed in the right arm. This was accompanied by general sweatings and considerable prostration. The affection of the arm progressed until the limb and hand became almost completely paralyzed. For several days there was great hyperæsthesia and a burning sensation complained of in the limb. This was followed by rigidity of the elbow joint, which became fixed at a right angle, and any attempt to straighten it caused considerable pain. The muscles were considerably atrophied. Improvement was gradual, and on the patient's discharge, about the ninth or tenth week from the onset of the fever, the limb had not recovered all its movements, and there was some atrophy remaining. Dr. Archer drew attention to the extreme rarity of these local paralyses in enteric fever, and remarked that when such complications do occur in the acute specific fevers, they are usually observed during the period of convalescence, and not in the acute stage.

Epilepsy Due to an Old Blood Cyst.

On the 22d of February (says the *Med. Press*), Mr. Kendal Franks operated in the Adelaide Hospital on a man, æt. 25, who had been subject to epileptic attacks for four years, the result of a fall of nine feet on the top of his head, in 1879. Part of the frontal and parietal bone on the left side had been depressed by the fracture. Immediately after the accident the patient had been unconscious for three weeks, but subsequently he had suffered no ill effects until the epileptic attacks came on, six years later. These recurred about once a month, although sometimes he had five or six a month. Under the use of bromides continued for a year and a half, he once had an interval of three months. Mr. Franks trephined the skull immediately behind the left frontal eminence, and on opening the dura mater discovered a cyst the size of a large walnut beneath it, with a corresponding depression in the brain. The cyst contained serum, and an old blood clot. This was evacuated, cleaned out, and drained. The patient recovered rapidly, and was allowed up on the twelfth day. Since the operation, he has had no return of the epilepsy. The full returns of this interesting case will be published when sufficient time has elapsed to judge of the permanency of the cure.

Infecting Whitlow.

Dr. Estéban Borrero Echevarria, writing in the Havana medical journal *La Enciclopedia*, mentions the case of a young woman of twenty-three, badly nourished and ill developed, appearing like a girl of sixteen, who had a whitlow commencing in the middle joint of the middle finger of the left hand, which, being neglected, went on to produce caries of both the distal phalanges, with serious deformity of the finger. In about two months after the commencement of this whitlow another formed in the second and third joints of the ring finger of the right hand. She then presented herself for treatment. Dr. Echevarria promptly opened the whitlow down to the bone, and this healed satisfactorily; however, in about a fortnight a third whitlow formed in the ring finger of the left hand. This was also opened. These three whitlows were all quite idiopathic. The writer does not attempt to explain the succession of these inflammations, but suggests that they may be considered as all due to a general vice affecting the whole system, or to infection through unnoticed abrasions of the skin by pus. Some, he says, may consider the case as one of infectious osteo-myelitis, but at all events he gives the facts as showing the existence of osseous panaris (*panadizo óseo*).

Decoction of Mallow in Leprosy.

Lepra maculosa is not universally recognized as a separate form of leprosy, entirely distinct from the tubercular and anæsthetic varieties. It is, however, considered to differ from these by Mexican physicians, two of whom, Drs. Lucio and Alvarado, have written a good deal on the subject. Quite recently it has been stated that a cure has been found for this form, Drs. Velasco and Egea having each successfully treated a very severe case in a hospital in Mexico (*Gaceta Medica de Mexico*). The remedy was very simple, and was suggested by Don Joaquin Rodrigues, a student, who had seen it used with advantage. I consisted merely of a strong decoction of a malvaceous plant which grows in gardens in Mexico, and is known there as the "ball of fire" (*bola de fuego*). Of this from one to two pints are given daily. In both the cases in which it was given a marked improvement rapidly occurred, recovery with cicatrization of enormous ulcers taking place in about four weeks. It is worthy of remark that these two patients, the one a man, the other a woman, were not in isolated buildings, but occupied beds in the general wards of the hospital, the authorities apparently disbelieving in the infectious character of leprosy.

Parencephalus.

Mr. Stocks showed a girl, aged 16½, to an English medical society, whose height was 40 inches, and who weighed 35¼ pounds in her clothes. During her intra-uterine life her mother had good health; both her parents were healthy. Since her fourth year she had grown very little. She had had measles, and what was said to be typhoid fever. Her intellect was about on a par with the development of her body; sometimes she would talk and at others not. She straddled in her walk, and had a tendency to walk on her toes. Her temporary teeth were shed in the usual manner, but had been replaced only by the incisor, canine, and first lower molar on the right side. There were no indications of puberty, save a slight development of the hips. She could tell her letters and spell short words. She occasionally became cyanotic, though there were no apparent cardiac lesions. Her development appeared to have been arrested when about

five years old. Her head was 19 inches in circumference.

Dr. Ross pointed out that the tendon reflexes were very marked, as well as ankle clonus, and that the case was one of parenphalus.

Retention of Placenta for Twenty-two Months.

Dr. Rangé reports in the *Journal des Layes-Femmes*, January 1, 1887, the following case: A woman, thirty years of age, primipara, had a miscarriage in September, 1879, at the second or third month of pregnancy, followed by severe and repeated hemorrhages. No doctor was called in, and little is therefore known of the circumstances or causes of the accident. The hemorrhage continued for some time, gradually getting less, and ceased entirely for four months, reappearing in April, 1880. Since that date the patient suffered constantly from severe abdominal pains, with red and white discharges, and a deranged state of the bowels. Matters mended to some extent, and the patient thought she was getting well again, when, in July, 1881, she was seized with labor-pains, and in two hours was delivered of a placenta in a state of putrefaction, about the size of the closed fist. She made a tedious but perfect recovery. This patient had had no marital intercourse since her miscarriage, and no doubt is therefore possible as to the reality of the placental retention having lasted twenty-two months.

Fracture of the Internal Epicondyle Treated with Splints.

Dr. G. T. Loomis, of Minneapolis, Minn., reports the following case to the *Med. Record:*

"H. D., aged nine, was thrown forcibly upon the ice, striking his elbow, and was brought immediately to my office. He was suffering severe pain about the internal condyle, which was increased by any attempt at extension, although the latter could easily be done. The arm was semiflexed, the point of the condyle being displaced downward one-half inch, and could be moved easily in any direction. I flexed the arm and reduced the displacement easily, and applied a bandage firmly, the arm being held in a sling. No pain and little swelling next day. The dressing was left in position one week, and the arm could then be extended about one-half. The bone remained in position. Passive motion was made nearly every day for four weeks, the arm swinging at the side without bandage. At the present time, two months after the accident, the boy can extend and flex the arm nearly as well as ever."

Quinsy.

Dr. Easby recently read a paper before an English medical society on quinsy and its treatment. After speaking of the old method of antimonials, free purgation, complicated gargles, leeches and blisters, Dr. Easby advised the use of aconite given after Dr. Ringer's method, or from ten to fifteen grains of salicylic acid or salicylate of soda given every two hours, which had invariably afforded speedy relief. Gargles were strongly condemned as both useless and cruel to the patient. As a local application, a powder consisting of equal parts of tannin and iodoform puffed on to the swollen tonsils he had found give great relief to the pain.

Dr. Latham agreed that gargles were useless, and advised the use of the spray, chlorine water, or some antiseptic. It was especially useful for children. He strongly endorsed Dr. Easby's remarks on giving salicylic acid and salicylate of soda in the early stage, more especially if there was any association of rheumatic symptoms.

Intra-uterine Amputation of Forearm.

Before an English Medical Society, Mr. Street said that A. B., aged twenty-two, a healthy young woman, was first seen by him when suffering from inflammation of the left olecranon bursa. From an inch below the elbow the limb is wanting, and the stump presents all the appearance of an intra-uterine amputation. On inquiry he found that she was born with this deformity; the stump was quite healed at birth, and no evidence of any remains was to be found. The cicatrix is very small, being only three-quarters of an inch long, and the skin is very little puckered around it; it is not adherent to the deeper parts. The bones of the forearm can both be distinctly felt, and the olecranon seems almost equal in size to the right one. The humerus and muscles of the left arm are no smaller than can be accounted for by not being so much used as the right arm. There is no history of syphilis in the mother, nor was any accident remembered during gestation.

Rhinitis with Spasmodic "Snorting."

Mr. Spencer Watson read notes before an English medical society of a case in which a young woman, aged 26, after a great men-

tal shock, was seized with spasmodic inspiratory "snorting," very frequently repeated. This soon became uncontrollable, and continued for many months, in spite of treatment, the spasm coming on sometimes every half-hour and sometimes every ten minutes during the day, ceasing, however, during sleep. Large doses of bromide were given with temporary good effect; but, on their being discontinued, the "snorting" soon recurred with its original intensity. On rhinoscopic examination, Mr. Watson discovered great thickening of the turbinated bodies, which were partially removed with very good effect. Subsequently, nasal plugs were used, and the nostrils were freely sponged with hazeline. The "snorting" had not recurred since the last operation (in January, 1887), and the smell and taste, which had been much impaired, were now perfect. The general health had also improved.

Mumps and Peripheral Neuritis.

Many diseases not strictly speaking of nervous nature have now been found to be associated with peripheral neuritis. Phthisis, typhoid fever, diphtheria, and other febrile diseases, are the best known of these. Mumps may be added to the list on the authority of M. Joffroy. The paralysis that occurred in Joffroy's case affected all four limbs. The legs, as usual were first affected. Lancinating pains preceded the paralysis. The deep reflex actions were abolished. The muscles gave the reaction of degeneration when tested with the faradaic and voltaic currents. The muscles appeared to be increased in sensitiveness, for slight pressure caused pain. The paralysis was observed first three weeks after the onset of the mumps. Is it necessary to ask whether the case was one of true mumps? Mumps is certainly complicated and sometimes followed by cerebral paralysis. In M. Joffroy's case the paralysis endured for four months. Iodide of potassium was the medicament administered.

Inhalations of Oxygen in Eclampsia.

Lvoff (*Journal de Medecine*, January 2, 1887,) describes the case of a primipara who was attacked with eclampsia at the beginning of labor. Delivery was effected with forceps; but the attacks continued, although chloroform and chloral were given. Inhalations of oxygen were then prescribed; but, in spite of this, the symptoms grew more serious, the attacks became more frequent, and the respiratory stertor increased. The patient was cured by subcutaneous injections of hydrochlorate of pilocarpine. Nevertheless, M. Lvoff recommends inhalations of oxygen in such cases, because, as he asserts, eclamptic attacks stand in direct relation to the accumulation of carbonic acid in excess and the want of oxygen in the blood, the latter circumstance being the cause of the diminished circulation, the greater arterial tension, and the disturbance of the circulation or nutrition of the nerve-centres.

Foreign Body in the Nose.

Dr. Hunt relates two cases in a foreign exchange. The first was that of a boy, æt. 4, who for eight months had had a fœtid discharge from the nose. On careful examination, the right nostril was found to be obstructed by a foreign body, which on removal proved to be a cherry-stone. The second case was somewhat similar, except that the offending body was a plum-stone, which was removed by forceps. He laid down the rule that in all cases of fœtid discharge the nasal cavity should be examined by the speculum (a bent hairpin, or two bent hairpins, formed a most effective speculum, not unlike Baber's). In case of a foreign body being present, it should not be removed by a current of water injected up the other nostril; this might get dammed up, and damage the middle ear. Cocaine was doubly useful; it not only acted as an anæsthetic, but it also reduced vascular turgescence.

Injury to Shoulder.

Before an English medical society Mr. A. F. Clay showed a man, aged 77, who had fallen down stairs on his shoulder; he was told by his medical attendant that he had "broken his arm high up." Three weeks after this, Mr. Clay saw him, and found his humerus and clavicle intact; but, about an inch and a half above the lowest part of the anterior boundary of the axilla, a round, hard prominence, the size of a marble, was seen and easily felt. It was slightly movable, but more in the lateral than the vertical direction. It followed the movements of the humerus. Since then it had become absolutely immovable, and was smaller. The coracoid process on the injured side was not so prominent as its fellow.

Warts—Remedy For.

Warts are amongst the petty annoyances of life (says the *Med. Press*), and few are capable of submitting to the annoyance with the

equanimity of "Old Noll." Amongst the latest remedies for the growth is the addition of 15 grains of corrosive sublimate to an ounce of collodion, and with this sublimated collodion the wart is to be brushed once daily. *Zeitschrift d' Oester. Apotheker*, v. A more safe and equally efficacious application is a saturated solution of the carbonate of sodium, common washing soda. After many trials, I have found it superior to all other remedies for removing warts.

The Aniline Treatment of Phthisis.

Dr. Kremianski's idea of curing tuberculosis by converting the blood into a dilute solution of aniline (see the *Lancet*, March 5,) has been tried by Dr. Nesteroff on a patient who was about to be sent to the south, with the result that he became rapidly worse and died in a fortnight. The Moscow Medical Society, before whom the matter was brought, were nearly unanimous in the opinion that the aniline treatment would be not merely useless, but positively dangerous.

The Gonococcus in Gonorrhœal Arthritis.

Dr. P. V. Smirnoff has examined the seropurulent fluid aspirated from the inflamed knee-joint of a patient, aged twenty-eight, in whom arthritis had developed about a month after his contracting gonorrhœa. Numerous groups of Neisser's microbes were found within the pus-cells. Hence the author comes to the same conclusion as Petrone, Kemmerer, and M. I. Afanasieff—that is, that the articular inflammation is caused by the gonococci entering the blood.

Excision of the Entire Clavicle.

Dr. John Sloan reports in the April number of *The American Journal of the Medical Sciences* a successful case of excision of the entire clavicle for central carcinoma in a boy aged fourteen years. Four months later there was evidence of the return of the cancer in the line of the cicatrix and in the glands of the neck.

Anal Fissure.

A one-in-fifty solution of chloral hydrate in water applied on a rag to the fissure immediately after the morning stool, is recommended by Dr. Crequy, in the *Therapeutic Gazette*. Its action as a stimulant to granulations, and as a local antiseptic, makes it very suitable in such cases.

Correspondence.

Puerperal Convulsions after Miscarriage.

Eds. Med. and Surg. Reporter:

On December 20, 1886, I was called to see Mrs. I. V., aged 20, primipara. Blonde, of small stature, but rather fleshy. Mother died in a convulsion some years ago. Symptoms: headache, pains in back and lower bowels, and wasting. I prescribed ergot for wasting, brom. pot. for headache, and to take 20 drops tr. opii for the pains every one and a half hours till easy. I heard no more of the case until December 31, a. m. She was taken in labor and delivered of a dead male child, partly decomposed. The placenta came away all right. I left her about noon, doing, I thought, as well as any woman I ever delivered. At 1:45 her husband came and said she had had a fit, and was dying. When I arrived she was rational; could talk; said her head hurt and she was sleepy. Pulse 130, face flushed, feet cold. I gave her 30 grains bromide of potash and 5 drops Norwood's tr. verat. viride, and applied mustard to feet. Slept till 2:30 p. m. Vomited and had another convulsion. As soon as she could swallow, I gave her 30 grains hyd. chloral, and went after my hypodermic syringe. She slept until 3:15 p. m. Vomited, and had a harder convulsion than before. I then gave hypodermically sul. morphia gr. $\frac{1}{12}$, verat. viride, drops 5. She slept until 4 p. m. Vomited and had a fourth convulsion. Before it was entirely off, I gave her hypodermically sul. morphia gr. $\frac{1}{8}$, verat. viride N. drops 10. She rested until 6 p. m. Vomited, and had a convulsion, and I repeated the last injection. She slept until about 10 p. m. Woke up and asked for water, and tried to vomit. I then gave her 30 gr. bromide of potash, to be repeated if very wakeful. Rested well through remainder of the night, and slept nearly all the next day. January 1, 1887, at 6 a. m., I gave a dose of comp. cath. pills. This, the seventh day of January, 1887, and eighth day of sickness, she is able to sit up in bed. I did not have a chance to examine the urine.

S. R. Humston, M. D.

Smithville, Ind., January 7, 1887.

A New Departure.

Eds. Med. and Surg. Reporter:

The Board of Governors of the Maternity Hospital have unanimously determined that the vacancy now existing in the visiting obstetrical staff of the Hospital should be filled

by a competitive examination. Dr. Edward L. Duer, Dr. Wm. Goodell, and Dr. W. H. Parish have consented to conduct the examination.

Those desiring the position must apply by letter before the 1st of May to Dr. Edward L. Duer, 1704 Arch street, Chairman of the Committee, and soon after that date the applicant will be notified of the place where and time when the examination will be held.

J. V. Ingham,
Chairman of Executive Committee.
Philadelphia, April 18, 1887.

News and Miscellany.

The Fifty-two Years' Plague.

The *Lancet* says, according to Procopius, "the Byzantine Herodotus," the plague began A. D. 542 in the Nile delta at Pelusium, and dividing its forces it attacked Alexandria and the rest of Egypt on the one hand, and Palestine on the other. Beginning always on the sea-shore, it penetrated inland, depopulating islands, caverns, hill tracts—wherever, in short, human beings were found. In its second year it invaded Byzantium in the middle of spring. Many of its victims felt themselves struck in some part of the body, when, by way of exorcising the assailant, they would utter some sacred word and hurry into the nearest temple. To escape the importunities of friends, others, again, would barricade themselves in their rooms and plug their ears so as not to hear the loud knocking at their doors. A feverish malaise arousing them from sleep or arresting them in their walk or at their work was the first symptom; but there was no change of color, or sense of burning heat, or inflammatory affection, so that in the evening neither patient nor physician was alive to any danger. But many on the same day or the day following, or a considerable time thereafter, saw a bubo rising on the groin, or in the armpits, or on the parotids, or in other regions, and this symptom was common to every sufferer from the disease. Somnolence, stupor, or acute delirium were often present, with forgetfulness of every call of nature, so that many who happened to be without attendants died of hunger. Contact with patients or with the dead gave the malady neither to physician nor to sexton, while many—they did not know why or how—were attacked and succumbed in a few hours. Patients flung themselves into the sea or from high places in anticipation of death, while in others the bubo, not preceded by visions of delirium, passed into gangrene, and they died in convulsive agony. The physicians, suspecting these plague ulcers to contain a poison which caused the disease, opened them in many dead subjects, and found them to contain a large carbuncle. Those cases in which the body was covered with black pustules, the size of a lentil, died within twenty-four hours, while others vomited blood till death relieved them. Errors in prognosis were infinite, able physicians foreseeing death where marvellous recovery supervened, and predicting recovery just before fatal collapse. Therapeutics were equally at fault. The bath was of use in some cases; worse than useless in others. It was quite as ineffectual to fly from the disease as to treat it—such was the ignorance as to its origin or its issue. Those in whom the bubos proceeded to copious suppuration got well, as with the defervescence of the carbuncle the signs of returning health revealed themselves. Recovery was not always, however, complete, the survivors being often afflicted with semi paralysis of the tongue, impairing distinctness of articulation for life. In Byzantium the plague lasted four months, during three of which it was at its maximum, when the mortality reached 10,000 daily, till the city seemed deserted. Other details confirmatory, with few exceptions, of the powerful description by Procopius fill in the sombre picture, and must be drawn from the histories of Agathias and Evagrius. Gibbon, in his condensation, followed with greater authority by De Renzi, contests the dictum of Procopius that the disease was non-contagious, an epithet scarcely applicable to a visitation which passed from country to country, beginning at the seaports and penetrating inland. Another point indicated by De Renzi is the evidence deducible from Procopius that the Byzantine physicians practiced morbid anatomy and sought out the causes of disease by pathological research: "Even the Christians of the sixth century did not hold the dead subject to be so intangible as not to afford to science the means of exploring the structure of the body, and so of aiding anatomy" ("Scuola Salernitana," vol. i., p. 31).

Foreign University Intelligence.

Basle.—Dr. Fehling, Director of the Stuttgart School for Midwives, has been appointed Professor of Midwifery.

Berlin.—Professor Karl Möbius of Kiel will take up the duties of the chair of Zoology after Easter.

Bordeaux.—M. Blarez (*agrégé*) has been appointed Professor of Chemistry.

Cracow.—Professor Hofmokl, of Vienna, has refused the invitation to Cracow on account of the wretched condition of the surgical clinic. The names of Drs. Rydygier and Obalinski are now mentioned in connection with the vacant surgical chair.

Giessen.—Dr. Spangel, Director of the Town Museum of Natural History, has been appointed Professor of Zoology.

Helsingfors.— Dr. Holsti has been appointed Extraordinary Professor of Internal Pathology, and Dr. E. Sundvik Extraordinary Professor of Physiological Chemistry and Pharmacology.

Innsbruck.—Dr. Borysiekewicz, of Vienna, has been appointed Professor of Ophthalmology.

Lyons.—M. Laroyenne, who takes one of the gynæcological courses, has been appointed Professor-adjoint. M. Perroud, who takes one of the courses on children's diseases, has also been appointed Professor-adjoint.

Munich.—Dr. Karl Schloesser, Assistant in the Ophthalmic Clinic, has become *privat docent.*

Nancy.—M. Hergott (*agrégé*) has been appointed Professor of Midwifery. M. Spilmann (*agrégé*) has been appointed Professor of Clinical Medicine.

Rouen.—Professor Duménil has been appointed Director of the Preparatory School of Medicine.

Tomsk.—The Medical and Physico-Mathematical Faculties of this the new Siberian University are to be opened this year.

Toulouse.—M. Charpy has been appointed Professor of Anatomy, in succession to M. Bonamy, decased.

Vienna.—Professor Max Gruber, of Graz, has been appointed Extraordinary Professor of Hygiene. It has been decided that the vacation courses are only to be open to foreign medical men in cases where the full number of the classes is not made up by Austrians. This may prove rather a serious matter for some of the English and Americans who frequent the Vienna Hospital for the short courses, for which it is famous.

Würzburg.—Dr. Matterstock has been selected by the Senate as successor to Professor Geigel, the recently deceased Professor of Medicine.

Peculiar Legal Evidence.

A young woman of Mercer county, Pa., swore out a warrant for the arrest of a man, claiming that he had choked her, and had almost dislocated her left wrist by twisting it. She was in the ninth month of pregnancy, and although the discharge of the defendant was looked for, owing to the absence of witnesses, the birth of the babe revealed what the justice considered sufficient evidence to convict the man on. The child showed the marks of a thumb and fingers about the throat, and the left wrist was twisted and swelled, as if from a sudden wrench. The *Med. News*, in commenting on the case, says:

"On general principles, we should say the judge should not have admitted the baby as testimony, and certainly no man should be convicted on such trashy evidence as is afforded by ordinary birth-marks."

The Profession in Austria and the Government.

The Austrian Medical Association, now comprising 4,500 members, recently held itsseventh annual meeting at Innsbruck, and resolved to petition the Government to make vaccination obligatory throughout the empire by imperial statute, also to restrict the privilege of private practice to medical men who have already served in a hospital. The Association expressed an opinion that considerable changes were desirable in the regulations concerning the training of medical students; and, lastly, a request was preferred that a law should be made assigning substantial pensions to the widows and orphans of medical men who might meet with their death through attending to their duties during an epidemic.

The Title "Doctor."

An official decision regarding the printing of the title "doctor" on United States stamped envelopes, postals, etc., has recently been rendered. A physician of New York city ordered one thousand stamped envelopes printed with the prefix "Dr." before his name. The New York post-office refused to allow the prefix to be used, holding that it advertised his calling. On appeal to the Washington authorities the decision was overruled, and the doctor was allowed to have his envelopes printed as he desired. The decision is manifestly the just and correct one, and we are glad to place it upon record.

American Public Health Association.

The fifteenth annual meeting of the American Public Health Association will be held at Memphis, Tenn., November 8–11, 1887.

The Executive Committee have selected the following topics for consideration at said

meeting: 1. The Pollution of Water-Supplies. 2. The Disposal of Refuse Matter of Cities. 3. The Disposal of Refuse Matter of Villages, Summer Resorts, and Isolated Tenements. 4. Animal Diseases Dangerous to Man.

These topics are exceedingly important, and apply to every section of the United States and the Provinces. Therefore, it is hoped that sanitarians, and others who have had experience and observation in these matters, will give their views to the Association, and through it to the public.

Official Representatives to the International Medical Congress.

Dr. Leopold Servais, of Antwerp, has been appointed by the Belgian Government as representative to the Ninth International Medical Congress (says the *Medical Bulletin*). More recently we learn that the Deputy Surgeon-General, Jeffrey A. Marsten, M. D., of the British army, has been designated a representative by his government; and the Government of France, through the Academy of Medicine, has designated as its representatives Drs. Charpentier, Dujardin-Beaumetz, Léon Le Fort, Trélat, and Vallin. From all directions, at home and abroad, the indications of a very large and brilliant assemblage are of the most gratifying character.

Packer's Tar Soap.

When we say that for years we have used Packer's Tar Soap in our family, and recommended it to numerous patients and friends as the most agreeable soap known to us for toilet purposes, and the most remedial in diseased conditions of the skin, we do nothing more than pay a just tribute to its merits. It is composed of pure materials associated with fresh pine tar, and both for its cleansing and hygienic properties deserves an extensive patronage from the profession and the public.

Another Jubilee.

According to the *Vratch*, on April 17th (29th), Professor S. T. Botkin, of St. Petersburg, celebrated the thirty years' jubilee of his professorship. His colleagues, disciples, and admirers made due preparations to honor the man whose serivces to the Russian medical profession cannot possibly be overestimated.

The Late Professor Schroeder.

An influential committee has been formed in Germany for the purpose of establishing some memorial of the late learned Professor Schroeder. A marble bust to be placed in the University Frauenklinik has been decided on as a part of the memorial, but its further development has not yet been determined.

A Giant.

According to the *Kievlanin*, January 27, 1887, a Greek, a Turkish subject, who recently died of pulmonary phthisis at the Simferopol Town Hospital, was 3 *arshins* and 5 *vershoks* (about seven feet and nine inches) in stature. He slept on three beds laid close together.

Items.

—Dr. Sinclair Coghill, of Great Britain, has been elected a Vice-President of the International Medical Congress, to be held at Washington on September 5th proximo.

—The British Association will this year meet at Manchester, and the session will commence on August 31. Sir Henry Roscoe, M. P., F. R. S., has been elected president.

—Buffalo claims a birth-rate of 31.5 per 1,000 in 1886; Rochester, which is very near, has a rate of 16.66 per 1,000. The *Buffalo Medical and Surgical Journal* says that there is some grave defect either in the vital statistics or in the fecundity of Rochester people.

—Vaccination is, it is stated, to be enforced among all the workmen employed on the coming Paris Exhibition. Each man will be vaccinated as soon as engaged, and the government will not only pay for the necessary medical treatment, but will continue the man's wages should his arm become bad and prevent him from working.

—M. Dupuis, of Brussels, has made a number of observations for the purpose of ascertaining the effect of vaccination on puppies, with special reference to its power of protecting them from the distemper. He found that it was quite possible to inoculate them with vaccine, but that it had no protective influence against distemper.

—It is stated on the authority of Dr. Grawitz, an assistant of Dr. Virchow's, that in as many as one-third of the cases of so-called muscular rheumatism which have been examined post-mortem, the presence of *trichina spiralis* has been demonstrated. In many of these cases the parasites must have been present in the muscles for many years.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

GREEN SPRING SANITARIUM,
AND
WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten aces. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and massage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

BELLEVUE HOSPITAL MEDICAL COLLEGE,
CITY OF NEW YORK.

SESSIONS OF 1887-88.

The REGULAR SESSION begins on Wednesday, September 21, 1887, and ends about the middle of March, 1888. During this Session, in addition to the regular didactic lectures, two or three hours are daily allotted to clinical instruction. Attendance upon at least two regular courses of lectures is required for graduation.

The SPRING SESSION consists of recitations, clinical lectures and exercises, and didactic lectures on special subjects. This Session begins about the middle of March and continues until the middle of June. During this Session, daily recitations in all the departments are held by a corps of Examiners appointed by the Faculty.

The CARNEGIE LABORATORY is open during the collegiate year, for instruction in microscopical examinations of urine, practical demonstrations in medical and surgical pathology, and lessons in normal histology and pathology, including bacteriology.

For the annual Circular and Catalogue, giving requirements for graduation and other information, address Prof. AUSTIN FLINT, Secretary, Bellevue Hospital Medical College, foot of East 26th Street, New York City.

THE RELATION BETWEEN DRINKING WATER AND TYPHOID FEVER.

BY DR. DOWLING BENJAMIN,
Of Camden, N. J.

Typhoid fever is caused by a peculiar and specific poison. I do not know that this is denied to-day by any one competent from careful study and thorough investigation to give trustworthy information on this subject. Does it arise "de novo?" All the investigations that I have made have proven to my mind that the poison which produces typhoid fever cannot be generated spontaneously, but must come from another case. I am aware that there are some physicians who, even now, believe that it originates "de novo," and they give the examples and cases which prove to their minds the truth of such belief. But the cases cited as proofs, in my opinion, are generally defective, and do not exclude the possibility of infection from a preceding case.

Take, for example, the four instances given by Dr. R. W. Hutchinson, of Queens county, N. Y., published so late as October 9, 1886, in the Medical and Surgical Reporter. I will not occupy your time by criticising all these cases, but will select the fourth, which seems to be the strongest, as follows:

"4. In the last part of August, 1885, a party of young folks, numbering some fifteen, started out to spend the day on the banks of a creek, near East Rockaway. They carried no water with them, but relied on securing a supply from a sunken barrel, near the creek, that had been used for a number of years. On this occasion it was noticed that the water tasted and smelled badly, so much so that some of the party refused to drink it. Exactly one week from the day of the picnic most of those who had drunk the water, some nine in number, were stricken down abruptly with typhoid fever. I regret very much that I did not have the opportunity of examining the barrel with its contents immediately after the picnic, as I am now left in doubt as to the cause of the decomposition in the water. Shortly after the outbreak of the fever, some person, fearing that others might drink, pulled up the barrel and destroyed the well. But, from a number of reasons, I can positively say that there was no possibility of the water being contaminated with the fecal matter of a patient suffering from typhoid fever, which is the recognized way of communicating the disease; and if the germs of the disease did not originate "de novo" in the well water, I ask the question—where did it come from?"

You see the doctor gives no reasons why the well could not be contaminated with typhoid fever, though he says he has a number of them—yet he says he had no opportunity of examining the barrel, nor its contents, but he *heard* some of the party say that the water tasted and smelled badly. Notice that in less than seven days most of the party of nine who drank of the water were suddenly stricken down. This fact, in itself, might occasion some doubt of the fever being a true typhoid, as the incubation period of typhoid fever is usually longer, though there are instances on record which would have a tendency to show that typhoid fever may occur with a shorter incubation period than two weeks. Two weeks, however, is about the usual time.

What a blessing it might have been if the doctor had only told us the precious little secret of how he knew that no one had been in that vicinity, whose fecal matter might have affected the well.

Then, take the cases cited by the illustrious Murchison, who has done so much for the thermometry of typhoid fever, but who has, perhaps, led astray more students on the origin of the poison than any other man. None of his cases are, in my opinion, conclusive, and this opinion is sustained, also, by the opinion of Dr. J. H. Hutchinson, of Pennsylvania, who says, in an article on this subject, that the cases referred to are by no means convincing. See page 256, "System of Medicines, by American Authors," just published.

The case put forward by the advocates of the spontaneous origin theory, as one of their strongest, is that reported by R. Bruce Lowe, Medical Officer of Health, Helmesley, Yorkshire, published in the *Brit. Med. Jour.*, in 1880. "It occurred," he says, "in a lad who had not been away from home for months. No stranger had visited the house, and there was no fever in the district;" but Mr. Lowe admits there was a case before, only eight months past, and only eight miles distant, and he does not prove there was no possibility of infection, either by domestic animals or by streams of water. It is a well known fact that when the great forests of pine are cut off the land, in the northern part of the United States, there comes up a thick growth of oak timber, immediately succeeding, and the common opinion of people who notice this strange phenomenon is that the little oak plants originate spontaneously in the soil. I think you will hardly believe this explanation correct, but the same agencies that sowed the original seeds in the forest, it must be admitted, are equally competent to sow the seeds of typhoid fever in unexpected places, occasionally, at least. The man who starts out in this stage of opinion to prove that typhoid fever originates "de novo" assumes a great a greater task than Hercules.

No combination, either of filth, fecal matter, or sewer-gas, has ever yet been discovered that will produce the disease.

What are the physical characteristics of the virus of typhoid fever? Is this virus a liquid, a solid, or a gas? Evidently it is matter of some kind. Inorganic matter may be either solid, liquid, or gas; organized matter is never liquid, never gas. We conclude it is not a gas for the following reasons:

1. The gas has not been isolated.

2. It would be more apt to go through the air than otherwise, which is not the case with this virus.

3. All known gases that affect the system profoundly, or that affect the system at all, do so at once, or in a few minutes after their reception into the system.

Can a dose of carbonic gas, ammonia gas, illuminating gas, or any other poisonous gas, be taken, and lie in the system for from two to six weeks, and then begin to develop a train of trouble—a uniform succession of symptoms, like typhoid fever, or small-pox, or any other of the zymotic diseases? Never. Is it a liquid—this virus? The same objections apply to this theory as to its being gas. Is it composed of solid particles? If so, these particles must be of nearly the same specific gravity as water. There is no evidence to the contrary, at any rate, and these solid particles must be very small, for water known to contain typhoid fever poison is often apparently clear and bright. Filters do not seem capable of sieving out these particles—these poisonous particles, and this poisonous matter. At least water has been filtered through ten and even one hundred feet of sand and earth, coming out clear, but still bearing the poison in sufficient quantities to produce fever and cause death. So far as is at present known, the poison has not been filtered out of the water by any kind of filter. This would lead us to think it was really dissolved in the water, but for the fact that a system of very fine filtration has not been tried upon suspected water, and then the water given to persons to drink, to see if the disease would be produced by it. There is no case on record of any person ever having taken the disease from water that has been boiled, thus showing that, as far as known, the boiling temperature destroys the poison.

The theory that the poison of typhoid is an organized poison, or germ, or bacillus, seems to explain its action more completely than any other.* This phase of the subject was carefully discussed, and its progress given at length by me in an essay written in 1876, and published in the *Country Practitioner*, volume 2, Nos. 6 and 7. Whatever may be considered the nature of this virus, the fact that water is its principal distributor is certain. Indeed, a careful study of the cases and statistics that I have examined, seem conclusive that at least 95 per cent. of the cases of typhoid fever come directly from the water. The poison which produces this

*Klebs and Eberth both claim to have discovered the bacillus.—*Philadelphia Medical Times*, Dec. 3, 1881.

disease does not go through the air. Physicians permit people to go into the sick room where the disease exists. Washerwomen have been known, in rare instances, to take the disease from the water containing the soiled linen, which has infected their hands and gotten into their mouths and absorbents.

The infected wash water is very often thrown on the ground near a well or into a sewer, with the more poisonous dejecta. I have seen two cases that occurred among sailors, who drank water from the Delaware river opposite the Philadelphia sewers.

There is one instance* where it has also been shown that cattle have been afflicted with this disease; but in tracing this disease still further back, it was found that the cattle caught the disease from drinking infected water. The milk supply has also been known to have been affected. So, the more we investigate the subject the more strikingly the fact stands out that water is the main habitat of the poison. Several facts show, also, that when water contains a little organic matter the virus will be active for at least a year, in still water, and very probably for a number of years, as some of the cases cited prove.

The ways in which a well, or a spring, or a stream, may become infected are so numerous and hard to trace, that sometimes they defy detection. For instance, a man may leave the city where typhoid prevails more or less at the time, and be either in the first stage of the disease, in a slight form, or convalescing, or be a walking case, perhaps not even knowing what is the matter with himself, getting out of his carriage or a railway car, taking his gun for a few hours recreation, and, as it so often happens, is seized with a desire for evacuation. This may take place in the vicinity of a spring, or stream of water, whence will thus start up one or more cases of typhoid fever, and the manner in which the water became infacted will never be known—will forever remain in doubt, and a mystery. Even the presence in that locality of this person may never become known, or they may have known of the presence of such a person and may have forgotten it. Recent investigations show the intimate relations of this disease to drinking water to be so close and so constant, that it is hardly ever worth while to think of any other source of contagion. One of the most remarkably clear examples of this relation of drinking water to typhoid fever occurred last year at Plymouth, a small city in Luzerne county, Pa., and for the invaluable lessons taught by this epidemic we owe much to the committee sent by the Mayor of Philadelphia to investigate the subject.

I quote from the report of the committee as follows:

"The mountain stream is a small one, running down over a rocky bed, and on a declivity not eighty feet from its bed a dwelling is situated, wherein, during January, February, and March, was located a case of typhoid fever, that is only now convalescent, the worst period of the case being about the 30th of March. The attending nurse was in the habit, during each night, of carrying the excreta from the patient and depositing it on the ground towards the stream. The ground, during all this time, was frozen, and covered with snow, until the thaw and rain already alluded to occurred. The poisonous character of the dejecta is not destroyed by freezing, but is only kept in a state of hibernation. A great part of the three months' accumulation of dejecta was suddenly swept into the rapidly-running stream, and reached the lower reservoir as quickly as a man walking fast would have arrived there.

"In fifteen days from this time the epidemic began, fifty cases occurring daily between the 10th and 20th of April. Up to the present 1200 people have been sick, and one hundred have died, out of a population of eight thousand. For the first three weeks the few people in the town who used well water exclusively escaped the disease. The period of incubation varies from ten to twenty days, or longer, and therefore no other conclusion can be arrived at than that the infective poison existed in the mountain stream water, and originated from the one case of fever in the house on the side of the stream."

This entire and comprehensive report is on file in the Mayor's office, Philadelphia.

Last October a severe epidemic of typhoid was in progress in Imlaystown, N. J., about forty miles from Camden, and I went out there to investigate it, and was greatly assisted in so doing by the kindness of Dr. H. G. Norton.

I found that a brook about four feet wide runs through the village. A street runs parallel with the stream about one hundred feet from it. A row of houses is situated between the brook and the street, and the back yards extend to the brook, about forty feet distant. Between the brook and the houses is situated a row of privies and a row of wells for drinking water. The privies are situated on the bank of the brook, so that the fecal matter from them has run into

* Kloten, Germany, 1878, Berlin, Klein. Wochenschrift.

the brook, a distance of only about four feet. The wells are between the stream and the dwelling-houses, and about thirty or forty feet from the brook. The somewhat impervious stratum has a slight dip towards the wells, and underlies the locality. On measuring it was found that the floor or the bottoms of the wells was not more than a few inches below the floor of the brook, and when the water was high in the brook it was also high in the wells. The soil was porous between the brook and the walls of the privies.

Beginning up street, and designating the houses, which are but a few feet apart—not over fifty feet—and numbering them "one," "two," "three," I will give you the following explanation:

In 1883 a family came to number one, suffering with typhoid malarial fever and diarrhœa. The children had fever and bowel trouble, with diarrhœa, lasting for months, until the spring of 1885. On August 4th, 1885, a young lady was taken with typhoid fever in this same house. On August 28th another young lady was taken with the disease in number two, the next house below, down the stream. August 27th a patient at number three took the disease. September 12th another patient took the disease in number three. In September a relative of the family in number two visited the town, drank the water, and died in a few weeks afterwards of typhoid fever. September 30th a patient opposite to number two took the disease. In the spring of 1886 the family had moved out of number two, the well had been kept closed and had not been cleaned out. A new family moved into number two in April or May, 1886. The boys drank the well water, in spite of protests, and took the disease in June, 1886. One of the brothers died. The girls, who would not drink the well water, escaped the disease.

An analysis of this water from the wells for the State Board of Health by Professor H. B. Cornwall, of Princeton College, showed the water to be thoroughly contaminated with fecal matter. Evidently the virus had remained in one of these wells; a year had passed, and yet the winter had not been able to kill it.

The length of time that the virus will remain active has not been ascertained, but it is known to be years, in water that is not much disturbed.

I have cited these examples because they are so recent and so near at hand. Hundreds of instances might be cited, and the evidences piled up *ad libitum;* but, if further examples would not be superfluous in this paper, the time allotted to me would preclude my citing them here. I might say now that much of the data upon which my remarks have been based is not included in this paper for the same reasons.

In the face of what is already known, I do not think any student of sanitary science can deny that the poison of typhoid may be carried by the water supply. I do not know that any do deny this, but the *extent* to which it is carried by water, and the preventability of the same, are the great points that do not seem to be sufficiently appreciated by us, and scarcely appreciated at all by the people in general.

If the people can be made to understand that almost all the cases of typhoid fever come from the water-supply, and that there is no disease more easily prevented than this, we shall have accomplished the first great step towards the annihilation of one of the worst destroyers of mankind.

Look at the dreadful suffering caused in Philadelphia and Camden to-day by ignorance or indifference to these facts. Only a few days ago a noble wife and mother died in our city of this dread disease, thus blighting the prospects of a happy family; and as I stood by her bedside I could but regret that another valuable life had been needlessly sacrificed.

The city of Camden had connected the water-closets and sewers containing the poison with the water-supply, and then distributed it thus laden with the deadly virus to the inhabitants of this city, but a few hours after it had left the deadly sewers. The husband of this lady, "as a lamb, dumb before his shearers, opens not his mouth;" so he paid his water tax to the city, his wife drank the dearly-bought "distillment," and gave up her life as the result.

Is there no redress? Is there no hope of escape for the people of these great cities? Must they continue to die by hundreds, as the death returns show every year, at a greater cost and expense than pure water could be procured for? Philadelphia also pours the poison into the cup, and then puts it to the lips of her most choice citizens, and kills off about seven hundred of them in a year, according to the official report.

The disease cannot occur without the virus to produce it, and the virus can be kept out of the drinking-water, and it should be kept out at any cost. It would pay at *any* price. Every death that is preventable is needless, and is a reproach to the community. Dr. E. O. Shakespeare, an eminent investigator of

contagious diseases, who has been sent abroad by the highest executive authority of the United States, to investigate the nature and causes of cholera, says, in the *New York Medical Journal*, in January, 1885: "That epidemics of typhoid fever are absolutely preventable and controllable, and neglect to employ proper means to this end should be regarded as inexcusable."

Great reforms and revolutions have taken place within our own recollection, and the student of sanitary science even dares to indulge the hope that even during his short life he may have the pleasure of seeing the death-rate from typhoid fever reduced more than ninety per cent.

INEBRIETY TRACED TO THE INTOXICATION OF PARENTS AT THE TIME OF CONCEPTION.

BY T. D. CROTHERS, M. D.,
Supt. Walnut Lodge, Hartford, Conn.

The physical health of the parents at the time of conception controls the future of the child to a large degree. An old writer said "that distempered and unhealthy children could often be traced to family broils at the time of conception." Dr. Downs, in his late Lettsonian Lectures, states that the physical health of the parents at the time of conception can be traced in the child; also that when the parents are disturbed in health, and their relations broken up, unhealthy children will be the result,

Exact facts in this field are difficult to obtain, but often the circumstantial evidence points out facts beyond all doubt. Dr. Russ relates that the miners of Westphalia, who live away from their wives, are generally intoxicated when they come home on visits. The result is that a large proportion of the children born of these families are idiots and feeble-minded.

Galton has pointed out some very curious facts concerning the children of professional men, which indirectly relates to my topic. He found from a study of the heredity of the members of some of the largest scientific societies of London, that the legal profession presented the most eminent men and the fewest idiots. The medical profession came next, and lastly clergymen, who produced the smallest number of eminent men, and the largest number of idiots and feeble-minded. The lawyers gave origin to six times as many more eminent men as the clergy. The clergy gave origin to six times as many more idiots and feeble-minded as the lawyers.

This curious fact evidently applies to Europe, where the clergy do not represent the brain vigor of the educated classes. It also indicates that occupation at the time of conception, as well as physical vigor, has a power over the future of the child. In the study of the heredity of inebriates, many cases appear where the parents were greatly disturbed in health and their social relations on or about the time of the conception of the child, which grew up and became an inebriate, without any special exciting causes.

In the following cases inebriety was traced directly back to the parents at the time of conception. While it is not a new fact in science, it is not often so clearly traceable; usually intoxicated states in the parents appear in idiotic, feeble-minded or defective children.

In the *first case*, the father was a sea captain; a healthy, robust man, who never drank except on shore, and then in great moderation. His ship went to China and the South Seas, and was away twelve or fourteen months at a time. He married in middle life; and, on returning from a long voyage, would go to his country house and be intoxicated with his wife for a week or more on wines—then recover, and start away again. His wife would drink with him, and be partially intoxicated. Several children were born, all of whom died in infancy except one, a boy, who grew up and became a periodic drinker, and came under my care. He was a nervous, melancholy young man, who could not follow any steady work long, and every two or three months he would rush away to a low house and secure some female inmate, and drink in the room to continuous stupor for days, then become exhausted, have gastritis, call in a physician, and quickly recover—then go back to the shipping-house where he was employed, and exhibit great energy and industry for a long time. His mind was unstable, and he was credulous of all things outside of his business. If he became angry and excited, he would stagger and talk like a man drunken, his face would grow red, the pupils of the eyes dilate, and the lids swell, and he would be more or less stupid for a long time. The approach of the drink paroxysm was marked by great business activity and anxiety to help some one. Then suddenly he would find a woman, and go away and drink as before. His early life was uneventful. He was a good student, of quiet, retiring manners, and held up as a model for his companions. At puberty he suffered from a low, nervous fever, of several weeks' duration.

He lived in his uncle's family, and had the best society and most temperate surroundings, when suddenly one day he disappeared. A week later he was found in a brothel, where he had been intoxicated from the time he came in. He gave no reason why he did this, and seemed indifferent to all counsel and advice. For a year after, he was temperate and exemplary in every respect. Then he disappeared as before, and drank wine in a room to stupor for a week or more, then came back. Then from this time these drink paroxysms were noted by the great secretiveness to go where he could not be found, and also by his never drinking until he found such a place, and a woman to join him. He was twenty-five years old when he came under my care. Two months after admission he ran away, and was brought back before he drank. He went to bed, and was more or less stupid on small doses of bromide of ammonia for ten days, then recovered. He seemed very sensitive to ten-grain doses of bromide. The next paroxysm was anticipated, and he was in bed a week with a low nervous fever and stupor. These paroxysms grew further apart, and finally merged in severe headaches, which gave way to simple remedies. He became heir to a large property, and finally married and went West. In this case a most striking similarity was apparent between the drink paroxysms of his parents, which were marked by continuous use of wine to stupor for days in a room alone. In his case, beginning at puberty, it seemed to burst out as an inherited impulse, using the same spirits, and lasting about the same time. It was not apparent that he was licentious at any other time, or even when drinking; the presence of a woman seemed all he cared for. His unstable, weak, nervous organization, and these peculiar drink paroxysms, pointed to the state of his parents at the time of conception. How the periodical drink manias of the parents should so impress the child as to be reproduced, antagonized by the circumstances and surroundings of life, is a mystery. Why he should suddenly, and without premonition, go away and drink to great excess in a peculiarly unusual way for a boy, and ever after keep it up at intervals under the same circumstances, can only be answered from a study of the heredity.

In a *second case*, the father was temperate, the mother had drank beer at meals all her life. After marriage, and for several days, both were intoxicated, and continuously under the influence of spirits, celebrating this event. Conception took place at this period. A little fretful child appeared, which cried night and day for the first year. By accident, whisky was found to produce the most perfect relief. From this time nothing but some form of spirits would allay the nervous irritation, and as he grew older he would cry for it, and refuse to be satisfied with any other fluid. At ten he drank beer regularly every night, and at puberty he drank to great excess. I was consulted. In appearance he was feeble and imperfectly developed. His mind was uncertain and changeable; he said the taste and effects of spirits gave him the greatest pleasure. When he could not get spirits he was delirious, and after using two or three glasses he became stupid, and laughed at everything until he fell asleep. He was placed in the care of a physician, who tried to withdraw the use of spirits by reducing it from day to day. After the spirits were withdrawn, he developed mania and delusions of persecution, during which he escaped from control and drank to stupor. The mania disappeared; again the effort to break up the use of spirits was tried, the mania returned more violent than ever, and the spirits were resumed and continued up to death, at twenty years of age. Three other children were born to this couple, who were temperate and of average strength and vigor. The parents never used any spirits after the first year of marriage.

In the *third case*, a man was placed under my care who had occupied a very responsible position of trust, and who with an insane indifference had drank to great excess, and forfeited all honor and respect. He was educated, and a man of talent and great energy. He was temperate up to forty years of age, when suddenly he drank to intoxication, and was seen on the streets shouting in a delirious way. In two or three days he became temperate, and seemed to have no regrets or sorrow for the past. He manifested no interest in the advice and counsel of his friends, and made no remarks of explanation, nor gave any reason for his conduct. Several months later he drank as before, and returned to his work with the same cool indifference as to his conduct and its consequence. He was forced to resign his position as officer of a bank, and gradually went down lower and lower, until brought to me. He drank periodically; the free interval being from three to eighteen months, the drink paroxysm lasting from three to six days. During this paroxysm he was maniacal, and reeled up and down the street, or was seen in an open carriage, always going where he was most prominent, and making

public speeches. He seemed possessed with delusions of power and grandeur, and placed himself in the most prominent places, interpreting the attention he received as evidence of his greatness. When he recovered he seemed to have a paralysis of all conception of the nature and character of his conduct. On all other matters he was clear and intelligent, but on this he was silent and reserved. He recovered, and went to the far west to live on a cattle ranch. In his history it appeared that his father, who was a temperate, healthy planter, married for the first time at forty. Soon after he drank to great excess, and was after this a periodical drinker until his death ten years later. His son, mentioned above, was conceived in one of these early drink paroxysms. The father was delirious at these times, and spent his time on the street and in prominent places, preaching and lecturing in a maudlin way. When he recovered he was strangely oblivious to any past conduct; said he did not remember or believe he was intoxicated. The later years of his life, he was very angry if talked to about drinking, and would not listen to any counsel or believe he drank to his injury. This drink storm always came on suddenly, and passed away after a short time, leaving the mind in a blank state of confused recollection of what he had done. In the case of the son, he seemed to have no realization that he had done anything strange or unusual, and listened with doubt and indifference to all that was said. The remarkable similarity of the symptoms of father and son, coming on at the same time of life, and following periodically, noted by delusions of power and grandeur, and desire to appear prominent, and the loss of consciousness of the past, or its relation to the present, in his own case, seem to indicate a direct heredity from father to son. These cases are sufficient to call renewed attention to this subject, and throw light on many of those unexpected outbreaks of inebriety that are a source of wonderment. Inebriety will always be a confused field of speculation, until it is made a special study by physicians.

ANOTHER CASE OF PERFORATION OF THE VERMIFORM APPENDAGE.

BY J. M'F. GASTON, M. D.,
Of Atlanta, Ga.

This contribution to the history of a lesion which ordinarily is not recognized in time to operate successfully, may aid to some extent in elucidating the obscurity connected with a differential diagnosis of the grave condition. The different phases of typhlitis, perityphlitis, and paratyphlitis, in the outset, correspond so nearly to the local phenomena associated with the initiatory stage of the inflammation preceding and accompanying perforation, that close attention to all the details of its development is of the utmost importance. It is evident from the comparative frequency of the cases reported latterly, that this accident has heretofore escaped observation, when peritonitis has supervened without resorting to operative measures, and terminated fatally, without any post-mortem examination. The symptoms which are associated with acute typhlitis correspond in most respects to those of perforation of the vermiform appendix, and the usual progress of the former being attended with more or less diffused inflammation, it is a difficult point to determine what may be the nature of the local trouble until the constitutional disorder has reached such an aggravated form as to preclude any expectation of relief by laparotomy.

The case now presented occurred in the practice of Dr. T. D. Lougins, who has kindly furnished me the following notes of his observations previous to my visit:

"I saw Johnny Caldwell, aged 13, February 28, at 7 p. m. Found him suffering with severe pain in right side of abdomen, located more particularly in right umbilical region. Thought I detected slight swelling at this point. I got following history: About twelve o'clock that day, while at school, ate raw potato. Came home at 2 p. m., complaining of pain in side, also of being very hungry, though ate very little and vomited soon after. Pain increased till I saw him. I administered morphia every fifteen minutes in one-eighth grain doses till one-half grain was taken. He then became easy. Left two grains calomel to be given at 12 o'clock, also one-quarter grain morphia to be given during night if pain returned, which was done. March 1, rested badly. No action from bowels; vomiting occasionally. Ordered four grains of calomel in two doses, to be given two hours apart. Bowels moved about 11 o'clock twice, discharging the potato inan undigested state. Pain continuing, ordered dose of castor oil, which was retained four hours and vomited up. Gave an enema, which passed off immediately, with no fecal matter, producing violent pain in testicle, which was relieved by applying hot cloth. Gave morphia during night. March 2, rested badly. Some fever and pain. Gave tr. aconite and morphia during day and night, until better. March

3, no action; pain less; more fever; anxious look; bowels very much swollen and tympanitic; much weakness; mother had given dose of salts before I saw him that morning; no vomiting. I thought the only chance was in an operation. Called in Drs. Bennett, Olmsted, and Crow, who agreed with me. We called Dr. Gaston.

Upon receiving substantially the foregoing account of the case, with a statement from the mother of the patient that very little of the fluid used for the enema was retained, and that he complained of pain in attempting to force it into the rectum, I was induced to make an exploration per anum. When the index finger passed within the sphincter the rectum was found to be enormously dilated, and to be occupied above by a protrusion of the large intestine, leading to the inference that there was an invagination of the lower bowel, and not simply a prolapse of the intestine. Moderate force with the finger did not succeed in returning it, and upon attempting to pass the point of my index finger within the canal I was unable even to verify the site of the opening. Each of my four colleagues was requested to make this exploration, and they all concurred in the view that the mass which was felt in the rectum was a protrusion of the large intestine. Upon consultation, it was determined to bring hydrostatic pressure to bear upon it, with the expectation of uniting the bowel to its proper relations; and the boy being placed in the knee-chest position, warm soap water, with a little salt and spirits of turpentine, was injected with a Davidson syringe, while the margin of the anus was secured with the fingers closely around the tube. After a time a portion of the fluid regurgitated, but the effort was eventually successful in replacing the protrusion. This was very evident to Dr. Olmsted and myself on examination.

Supposing that the symptoms indicating an extension of inflammation throughout the cavity of the abdomen might have resulted from constriction of the sigmoid flexure of the colon, which had become invaginated and passed into the rectum, we were now encouraged to hope for relief by the release of this portion of the large intestine; but it was understood that Dr. Longino, who remained in charge of the patient for the night, should advise the rest of us at daylight next morning of the condition of the patient. Not receiving any message before sunrise, I telephoned a neighbor of the family, and learned that the patient had died at 3 o'clock a. m.

It occurred to me as very desirable to get such elucidation of the obscure points in this case as would be afforded by an autopsy; and after overcoming the obstacles in our way, the post-mortem was made by Dr. Crow and myself, with the presence of all the physicians who were in attendance on the previous evening. The first step was to verify that the bowel had not descended again into the rectum, by a digital examination per anum; and after opening the abdominal wall by a careful inspection of the descending colon and sigmoid flexure, even extending to the rectum, it was very perceptible that the lower portion of the bowel had become inflamed and somewhat thickened by the previous constriction from which it was freed.

Upon turning our attention to the condition of the abdominal viscera, adhesions were found between the great omentum and the small intestines, with their mesenteric attachment agglutinated to the coils that were superimposed. To the right of the median line the peritoneal surfaces of the viscera and parietal wall were adherent, so as to require a forcible separation. Upon carrying the exploration into the ilio-cæcal region, an effusion of a sero-purulent dirty fluid was encountered which penetrated upward along the ascending colon to its curvature, and was confined by adhesions in front of the colon to this locality. The tissues surrounding this collection were thickened and almost necrosed, and the gall bladder was distended so that it reached downward to some distance below the margin of the liver, and was in contact with the upper boundary of this foul accumulation of decomposed matter. Upon a minute examination of the small intestines, commencing at the ilio-cæcal attachment and passing the fingers along every portion, nothing unusual was discovered, until within a few inches of the duodenum it was found to be held down by a band, and above this constriction the duodenum presented signs of inflammatory engorgement and thickening of its walls, which, however, did not seem to involve the pylorus. The liver presented an increase in the size of the left lobe, extending across the epigastric region.

Turning again to the ilio-cæcal region, the vermiform appendage was found enlarged, and with a dark-red hue throughout its entire length, being straitened out in a right line from the cæcum. About midway between its attachment and the end there was a perforation, caused by the sharp point of an ovoidal fæcal concretion, about ¼ inch in diameter and ¾ of an inch long, which was forced out of the cavity by the fingers

through the opening. There had evidently been an escape of the contents into the peritoneum for some days, so as to have caused the extension of its septic influence to such a distance, and the peritonitis was an effect of the local irritation from its pressure.

The question which naturally presents itself in connection with the history of this case, and the developments of the autopsy, as to the indications for laparotomy, is that, if warranted by the symptoms at any stage of its progress, whether an operation could have been resorted to with any prospects of success after the tenderness and meteorism led to the conviction that general peritonitis existed.

At the time I first saw the patient, it is clear that laparotomy could not have averted the fatal result, and it was a subject of congratulation that no operation was undertaken. But the issue must be squarely met by surgeons, as to the diagnosis of such perforations at an early period, and the practicability of removing the appendix and suturing its cæcal attachment, with thorough antiseptic treatment of the adjacent tissues; and this report may aid in solving that problem.

Medical Societies.

THE NEW YORK NEUROLOGICAL SOCIETY.

Stated meeting, April 5, 1887.

The President, C. L. Dana, M. D., in the chair.

Report of a Case of Sarcoma of the Brain (Occipital Lobe) Causing Hemianopsia, Removed by Operation.

By Dr. W. R. Birdsall and Dr. R. F. Weir.

Dr. Birdsall gave the history of the case, of which the following is an abstract: The patient, a Hebrew, aged 42, first came under his observation October 16, 1886. He had always been healthy until the summer of 1885. He denied injury to the head, or venereal disease. In August, 1885, he observed for the first time unsteadiness of gait, and had a severe attack of vomiting. Soon after diplopia for distance and increased awkwardness in walking was observed; also a disagreeable sensation akin to numbness, in the right leg, hand, and shoulder, but not in the face. This and the diplopia were transitory. Headache, usually frontal, was present occasionally, but never severe. October 7, 1885, he consulted Dr. E. C. Seguin, who found the eye-muscles normal (no diplopia with red glass). Left pupil a trifle wider than right; both active; fundus normal. Left lateral hemianopsia, vertical line passing little to left of fixation point. No paresis of tongue, face, or limbs; no anæsthesia; patella reflex normal; walk somewhat staggering, with decided tendency to the right.

October 20, diplopia had recurred; left externus weak; hemianopsia the same; no hemiopic pupillary reaction. Grasp of right 42°, left 30°.

November 7, beginning neuro-retinitis. Drowsiness during the day. Difficulty in rising from chair.

Diagnosis.—Tumor of mesal aspect of right occipital lobe, involving primarily the cineus, extending downward toward the tentorium cerebelli, and perhaps also upward toward the para-central lobule (leg centre).

Treatment.— Large increasing doses of potassium iodide.

From January to July, 1886, patient under care of late Dr. McBride. During the early months of this period his diplopia disappeared, and never returned; his gait improved somewhat, but had two attacks on street, feeling he could proceed no further, and staggered toward the left. From September on, his difficulty in rising, standing, and walking together with drowsiness, rapidly increased. In October, 1886, Dr. Birdsall found double optic neuritis, most marked in left eye; left pupil somewhat larger than right; no diplopia; no ocular paresis present. His movements were clumsy rather than ataxic; at times being accurate, at others wide of the mark, especially in left extremities; gait slow and uncertain. There was frequent expectoration of a viscid saliva. Left hemianopsia, Dr. Birdsall thought, could be accounted for only by a destructive lesion in the neighborhood of the gyrus cineus of the right occipital lobe. The locomotory disturbances appeared to him to be due to pressure effects of a tumor or structures below the tentorium, thus implying a growth of considerable size. His disturbance of equilibrium continued to increase in a very irregular manner. His intellect was not impaired. His family observed no change in his character or disposition. He was extremely uncomfortable mentally. An operation was proposed in February, 1887.

The operation was performed by Dr. Weir. Regarding the tumor Dr. Birdsall said it was of so large size, so much of the occipital lobe was compressed by it, that the case was of

little value for determining the limitation of the visual area in the occipital lobe. The growth was a sarcoma, originating in the meningeal structures, producing destruction of the cerebral tissues by pressure alone. Absence of severe headache should be noted, as it is usually a prominent symptom of tumors involving the meninges. One of the most important lessons that the study of cerebral tumors taught was that growths remaining limited to the meninges may attain a large size before disturbing the functions of neighboring parts of the brain. In these cases regions away from the tumor may give signs of importance before those in contact with the tumor. The extreme fatality of intracranial neoplasms was high warrant for taking an extreme surgical risk. The cooperation of neurological science and surgical art in the present state of each could hardly fail to build up an experience which would in some cases save life that would otherwise be lost.

Dr. Weir described the operation, which was performed March 9, 1887. Special antiseptic precautions prior to and during the operation were taken. The periosteum was raised, two openings were made with the trephine, the first one an inch above the occipital protuberance, and the same distance from the median line, the other immediately above; the openings were joined, and enlarged by the Rongeur forceps to two and three-fourths inches by two and one-fourth inches. The dura mater divided two-thirds the extent of the bone opening, its retained attachment being toward the median line. The tumor has at once recognized, and enucleated. It was necessary on account of its large size to incise it and press out some of its substance before it could be completely detached and removed through the opening. A great deal of venous bleeding took place, and sponges were stuffed in for temporary pressure; the cavity was inspected by the electric light, and showed that a great amount of pressure had been exerted upon the brain; the falx was crowded to the left of the median line; the tentorium was depressed to a horizontal line. The tumor weighed five and a fourth ounces. It measured three and a fourth by two and three-fourths by two and one half inches. One of the bleeding points was found to be in the region of the straight sinus, not free enough to be from that vein, but probably from the pedicle of the tumor; the other, apparently arterial, probably from a terminal branch of the posterior cerebral artery. The flow from each was readily checked by direct pressure, and it was determined to control them by packing the cavity with idoform gauze. The dura mater was partly united over the gauze by loose sutures. The operation was well borne until the final enucleation of the tumor, when the pulse fell, apparently from loss of blood. Some hours afterward slight diverging strabismus of the left eye was noticed; blood stain appeared through the dressings; the pulse was weak; stimulants were given; the patient was restless. At night transfusion of a saline solution was made with temporary improvement, and the dressings were removed to control hemorrhage which was seen to be taking place in a small stream; but the pulse again gave out, and nothing further could be done than reapply pressure in the supposed direction of hemorrhage. Death occurred at 2 a. m. An autopsy was not allowed, but in the lower part of the brain cavity was seen a large collection of coagulated blood.

Dr. Weir said that in another case, where the hemorrhage was from vessels too deeply situated to apply a ligature, he would control it by leaving on clamp forceps to be removed after a period of 24 or 48 hours. The opening, although large, was not sufficiently large to enable him to remove the tumor entire. It was intended to adopt Macewen's method, and employ bone drafts. Dr. Weir had recently replaced the pieces of bone removed by the trephine in a case of epilepsy, the opening being nearly two and a half by three inches; and now, about seven weeks after the operation, the wounds had healed save one, and the bones were felt to be solid, and were painless. Brief reference to the cases of tumors of the brain for which operations had been performed was made.

Report of a Case of Cyst of the Brain, with Operation.

Dr. Graeme M. Hammond related the case. The patient, a married woman, complained of severe pain an inch above the right ear, and had left hemiplegia. At the time her symptoms began she was about 29 years of age; she had had four children; during the progress of her disease she had a fifth child. All were strong and well. Her sickness lasted about two years and a half. It commenced by sudden loss of consciousness, and convulsions limited to the left side. The left side of the face became, and remained, paralyzed. About a year later she noticed gradual loss of power in the left arm; things dropped from the hand. At the end of another year the left arm was completely paralyzed. She then noticed increasing weakness in the left leg. When Dr. Ham-

mond first saw her she was able to stand and walk slowly. While the paralysis was extending she had four or five epileptic seizures, confined to the left side. Headache developed about the time the legs became affected, grew more constant, and was described as agonizing.

She denied syphilis. Physical examination showed loss of motion on the left side of the face, tongue, and soft velum, of the left arm, and partial loss of motion in the left leg. There was no disturbance of sensibility of any kind. The reflexes were exaggerated on both sides. Sight, hearing, smell, and taste were normal. Choke disc on both sides was observed at a subsequent examination.

Under treatment the headache was controlled to a considerable extent. Dr. Hammond's diagnosis was probable cerebral tumor, involving the cortical or sub-cortical substance of the motor centres. An operation was refused. The patient grew worse until the 20th of March, 1887, when her husband asked that the operation be performed. Dr. Spitzka then saw the patient with him, and made two examinations. He rather coincided in the diagnosis. The operation was performed in the hospital last Wednesday. Dr. H. Josiah Roberts assisted at the operation, removing the portion of skull by his electro-osteotome. Four buttons were removed by the electro-trephine; these were connected by straight lines made with the circular saw. The diameter of the opening was over two inches. A crucial incision was made through the dura. A hypodermic needle was introduced in different directions, but no fluid was withdrawn. The dura was closed, a drainage tube was introduced, the skin flaps were sewed up, the patient was put to bed. She lived only twenty-four hours, remaining unconscious after the operation. Prior to the operation she had become completely paralyzed in the left lower limb, she had delusions and hallucinations, she talked incoherently; bed sores developed.

The autopsy showed little hernial protrusion at the wound; the cortical substance here was thin. Incision through the motor region revealed three cysts in a line, deep in the white substance. The fluid in the cysts had been only partially examined; it was serum, and contained broken-down brain substance. The cysts were close together, and in a position to affect the face, arm, and leg centres. He could not explain why the syringe failed to bring forth fluid, unless it was that the cysts were too deeply striated or the needle passed between them. He added to the clinical history that the head was drawn to the right side the last three days of life.

Dr. E. C. Seguin was partly responsible for the operation in the first case, but it seemed the patient would not live more than two or three months without it. He expected to find a large tumor, but was somewhat surprised to see it encapsulated and non-parenchymatous. During the early history of the case the symptoms pointed to destruction of brain-tissue. He asked Dr. Hammond whether the sensory or motor symptoms determined the seat of his operation.

Dr. Hammond replied that the headache corresponded to the centres for the motor symptoms, and the seat of the operation.

Dr. Seguin added that the seat of the pain would be a very uncertain indication for the seat of the operation. In some cases of cerebellar tumor, for instance, the pain had been mostly frontal.

Dr. E. C. Spitzka, referring to the case reported by Dr. Birdsall and Dr. Weir, said that an artery large enough to cause fatal hemorrhage entered the gray and white substance of the right occipital lobe. It had been overlooked in many text-books.

Dr. Roberts explained how the circular saw could be used without injury to the brain, and the operation of the electro-osteotome.

Dr. Starr suggested the desirability of an analysis of reported cases of cerebral tumors for the purpose of determining their rapidity of growth and size.

Dr. R. L. Parsons read a paper entitled

Nomenclature in Psychiatry: Monomania or Oligomania, Which? Paranoia, What?

An examination of the reports of fifty-one asylums for the insane, taken at random, showed that of the whole number of patients enumerated less than two per cent. were classified as cases of monomania, while in twenty-four of these reports the term did not appear. But, however much systematic writers on the subject of insanity deprecated the use of the term monomania, they rarely succeeded. There were manifestations of insanity which were neither melancholia nor dementia, but which differed so much from mania that another designation was required for them, and the objectionable term monomania was the only one generally employed. Dr. Parsons thought a suitable substitute could be found. Paranoia had been used to a considerable extent, but if the meaning of the term monomania was too narrow for the

purpose required, that of paranoia was too broad. "In conclusion, then, with the assumption that monomania, as defined and explained by certain writers on psychiatry, designates phases of insanity of sufficient importance and well enough differentiated to require a place in the general classification of mental diseases; and with the further assumption that the reasons adduced in this paper are sufficient to justify the substitution of the term oligomania for monomania, it only remains to apply the proper meaning of the latter term to the former, to wit: A form of insanity which, although potentially affecting all the mental faculties and operations, apparently involves only a part, as the intellect, the emotions, or the will, or certain manifestations only of a faculty of the mind, which originates in the intellectual faculties rather than in the feelings, and the manifestations of which are well-defined, persistent, dominant, and systematic in character."

THE CLINICAL SOCIETY OF MARYLAND.

Stated meeting, held March 18, 1887.

The 190th meeting was called to order by the president, Randolph Winslow, M. D., in the chair.

Dr. A. Friedenwald exhibited a specimen and related a case of

Osteo-Sarcoma at the Base of the Skull.

The patient was a female, æt. 57 years, who had never borne children. She came under his care August 27, 1884, complaining of great pain in the head, which had troubled her for two months previously. Left side of the face was congested. Impairment of vision for two weeks. Partial ptosis of both eyes, more marked in left than right. Divergent paralytic strabismus in both eyes; pupils of normal size; no reaction of pupil in right eye; in left eye contracted slightly on admission of bright light. Had vertigo about one year ago. Unsteadiness of gait. Ophthalmoscope showed atrophy of the optic nerve in right eye. Pallor of disk and slight attenuation of vessels in left eye. Diagnosis of tumor at base of brain. He had the patient under observation till March, 1885. Muscular movements restored in right eye. Only partially so in the left. About this time a polypus presented itself in the left nares, which was removed. Shortly after this the superior maxillary and malar bone became hypertrophied. The sense of smell was the first of the special senses affected. Diagnosis was then made of tumor at the base of the skull. Autopsy showed a large tumor situated outside of the dura mater, within the skull. It involved the left half of the cribriform plate and the posterior parts of both fossæ. The tumor closely encircled the optic nerves and the nerves of the middle fossæ. It extended downward, through all of the bones which it covered, entirely absorbing them and leaving minute osseous granules throughout the tumor. It extended into both the nasal and orbital cavities. Microscopical examination showed the tumor to be a sarcoma.

DISCUSSION.

Dr. John Chambers said that he had once observed a case similar to the one reported by Dr. Friedenwald. The patient was about 22 years of age. He had suffered greatly with facial neuralgia, which finally subsided. The muscles became atrophied and were drawn to one side. Swallowing was very difficult. Autopsy showed the presence of an osteo-sarcoma, of the spindle-cell form, which occupied the wing of the sphenoid bone. The fifth nerve was incorporated in the growth.

Dr. L. McLane Tiffany related a most interesting case of

Nephrolithotomy.

The patient was a female, aged 25 years, and in the third month of pregnancy, upon whom he had performed successfully the operation of nephrolithotomy.

DISCUSSION.

Dr. John Chambers asked Dr. Tiffany if the patient had been subject to renal colic.

Dr. Tiffany replied that there was history of pain in the loin, but none of any calculus having passed. So the pain was attributed to the presence of stone in the kidney.

Dr. R. Winslow asked if there was any swelling in the side of the patient.

Dr. Tiffany replied that an examination was made under chloroform, and no enlargement of any kind was revealed.

Dr. S. T. Earle read a paper entitled

Two Cases of Tetanic Convulsions from Muriate of Cocaine.*

DISCUSSION.

Dr. R. Winslow asked Dr. Earle the size of the dose of the drug used.

Dr. Earle replied that two grains were used in the first case and five in the second.

Dr. I. E. Atkinson said a case had been reported where tetanic symptoms followed when only one grain had been given. A

* See Maryland Medical Journal, March 12, 1887.

German author had also reported a case where these symptoms followed its use. In both cases the drug was administered hypodermically. He thought these tetanic convulsions evidently belonged to the toxic effects of cocaine.

Dr. A. Bond asked Dr. Earle if there was any difference in the preparations of the drug used? and if he thought the location where he administered it had any influence on its action?

Dr. Earle replied that the preparations used were exactly the same. He did not think the location had anything to do with it. He gave it hypodermically into the connective tissue around the arms. In referring to the remarks of Dr. Atkinson, he said that he was always on the lookout for the toxic effects of cocaine whenever he gave it. As much as 40 grains had been given without bad results; but as these symptoms do occur, it is well for us to vary the dose in individual cases, a fact which he always observes.

Dr. G. Rohé had removed several wens from the head of two patients, mother and daughter, under the influence of cocaine. The mother did not feel the cutting at all, but had fainting symptoms to come on. He thought it due to the fact that the mother was probably more emotional than the daughter.

Dr. R. Winslow had seen a similar case where fainting symptoms were produced in a patient not all emotional.

Dr. John Chambers had once seen a man in a very emotional state from one grain given hypodermically. He tried a two-grain solution locally on his own gums for the purpose of having a tooth drawn, and it produced very peculiar symptoms about his legs. As the dose seems so uncertain, he asked if it is not safer to use ether or chloroform? They are less dangerous, as comparative statistics seem to show.

Dr. Earle said by experience he finds that he can get along with much smaller doses.

Dr. Winslow asked Dr. Gorgas if cocaine was used to any extent in dentistry?

Dr. Gorgas replied that his father had employed it both locally and injected into the gums, but it did no good.

Dr. Atkinson said hypodermic injections of cocaine for minor operations on the skin can be done very satisfactorily. He related a case where he had scraped an epithelioma of the face and the patient did not feel the slightest pain. He would not feel like discarding it from use.

Dr. W. H. Norris had often used cocaine very satisfactorily. In one case, a female, he introduced a catheter without the slightest pain, where it was impossible to do so before the drug was used. He did not think that fainting symptoms were always due to cocaine. He had observed them where none of it was used.

Dr. Rohé has used it on the surface of the skin for electrolysis, in five per cent. solution. Some modification of sensation was produced, though slight. Epithelium of the skin seems to prevent absorption. He had used injections for scrofuloderma, and did not get good results. Thought it due to the fact that he injected it into the tumor substance instead of around it.

Dr. Craighill thought the temperament of the patient should be considered. He had a patient to faint in his office while percussing his chest for examination for life insurance.

Dr. Samuel Theobald had obtained good results on the skin from injections of cocaine. He had had two patients upon whom he operated for cleft nose with good results. He also had used it on the eyelids with satisfaction.

Dr. Winslow asked Dr. B. B. Browne if he had ever used cocaine in the vomiting of pregnancy.

Dr. Browne replied "Yes," and in other forms of nausea very satisfactorily. He gave it in the dose of ten drops of a 2 per cent. solution.

A New Probe.

Dr. Samuel Theobald then described a probe, which he now uses, made of aluminium. It has the advantage over silver of being lighter and more slippery. He related a case of stricture of the nasal duct in a patient who lived in the country, and who could only come to see him occasionally. Each time she came the duct would be closed. He taught her to use the probe herself, which she does with ease, and she is now nearly well. Patients must be kept under observation in order to bring about cure.

Concussion of the Spinal Cord.

Dr. R. M. Hall related the case of a man, driver, who had jumped from a wagon with 75 pounds of glass in his arms. It produced great pain in the lower extremities. When he first saw him, patient was stiff from the abdomen down; no nausea. He administered an anodyne to him. The next day pain still great, and manipulation produced intense pain below Poupart's ligament on the right side. The day following the left leg moved with ease; right still stiff. He con-

tinued to grow better on anodynes. He made a diagnosis of concussion of the spinal cord, and asked the opinion of the members of the Society in regard to it.

DISCUSSION.

Dr. I. E. Atkinson said that judging from the description Dr. Hall had given of the case, he thought the diagnosis was correct.

EDITORIAL DEPARTMENT.

PERISCOPE.

On a New Acid found in Human Urine which Darkens with Alkalies.

Dr. Robert Kirk thus writes in the *Brit. Med. Jour.:*

About two years ago I met with a family of which three members had, from their infancy, passed urine giving the reaction of Bödecker's alcapton (*Annal. der Chem. und Pharm.*, cxvii., or New Series, xli., 98), assuming a dark color and greedily absorbing oxygen when rendered alkaline. All were boys, one of whom had died of whooping-cough, at three years of age; of the remaining two, one was a lad of 8 years, and the other an infant. The only other member of the family was a boy 10 years old, whose urine was quite free from the peculiarity which that of the others presented. Both parents were healthy, and their urine was found quite normal; but there was a history of jaundice and biliousness on both sides. The baby was large and apparently robust; the other two, however, had always been more delicate than their eldest brother, whose urine appeared to have been always normal. The most noteworthy symptom about the two who passed the peculiar urine was very frequent but painless micturition, which was also recorded in Ebstein and Müller's case (*Virch. Archiv.*, lxii., 554). The majority of the cases already published have been in children: I learned from Dr. Armstrong, of Dublin, in whose practice the last of these occurred, the interesting fact that another child of the same parents, since born, voids the same kind of urine. A comparison of some points in the present case, with those previously recorded, would be of interest, but cannot be attempted in this brief paper; neither can I do more than mention the investigations of Bödeker, Ebstein and Müller, and, lastly, of Dr. Smith, of Dublin (*Dublin Med. Jour.*, vol. ii., 1882, p. 465), the latter of whom examined the urine in Dr. Armstrong's case. In all these instances the urine was characterized by the same general reactions.

I commenced an investigation of the urine in the present cases in 1884, and had often the coöperation of the Rev. Mr. Gibson, of Partick, who is well versed in practical chemistry. The urine presented the following general characters. When rendered alkaline it assumed such a dark-red color that it required dilution with several volumes of water before it became translucent. On one occasion 10 cubic centimètres of it, of specific gravity 1014, when alkalinized, absorbed 7.8 cubic centimètres of pure oxygen over mercury; another sample of specific gravity 1019, absorbed 10.2 cubic centimètres of oxygen. It always reduced the copper test, its action on it corresponding to that of 8 or 10 grains of sugar to the ounce, as estimated by Dr. Pavy's ammonio-cupric method. It was either pale, almost like water, or of a peculiar brown tint, and never of the color of normal urine. The amount of urea was never in proportion to the specific gravity. The result of one determination with the ureometer was 1.26 per cent (specific gravity 1016); of another, 1.4 per cent. (specific gravity 1019); of a third, 1.68 per cent. (specific gravity 1028). The uric acid was estimated roughly a few times by hydrochloric acid, and seemed little more than a trace. Judging from the color of the urine the urobilin seemed to be nearly altogether absent, and the quantity of indican was never found to be above the normal. The urine was always free from albumen and sugar, being entirely without action on Lowe's bismuth solution. In all these points our urine corresponds closely with what has been recorded of previous cases.

In our first attempts to isolate the body which communicates the characteristic reactions to this kind of urine, we repeated all the experiments of Ebstein and Müller, and found that we could obtain essentially the same results. We found further, however, that our urine, and the substance we obtained from it after their method, presented those characters which identified it, as pointed out by Professor Smith on the authority of Preusse, with protocatechuic acid, and distinguished it from pyrocatechin, and which led Professor Smith to conclude that he had

found the former of these in his case. These were, that in alkaline solution it was insoluble in ether; that it did not pass over with watery vapor when distilled in an atmosphere of carbonic acid; and that it gave a green color with ferric chloride, which turned dark red on the addition of ammonia Nevertheless, we could not rest satisfied with the result, although convinced that we had the same body to deal with. A few points suggested doubt, and the necessity for further inquiry. Ebstein and Müller state that their pyrocatechin gave first a green, and then a brown color with alkalies; and that, on shaking up the urine with ether, a little of the pyrocatechin passed into the latter. Now, our urine never gave a green, but on shaking up with ether we obtained a product which gave a very distinct green with alkalies before becoming brownish red. Here was a difference which called for explanation. Again, we could hardly regard the green color with ferric chloride satisfactory proof of the presence of protocatechuic acid; it was but a pale grass-green, difficult to catch, and readily disappearing in excess or with agitation. The urine in Professor Smith's case, morever, had been analyzed by Professor Tichborne, who noted an action on the sugar test corresponding to eight grains of sugar to the ounce, and who did not fail to remark the small amount of urea in proportion to the specific gravity, namely, 1.2 per cent. with specific gravity 1025. Protocatechuic acid has no action on Fehling's solution; and it must be pointed out, as a defect in Dr. Smith's investigation, that he did not put this to the proof with the isolated product of his analysis. Further, the same urine was subjected to a spectroscopic examination by Professor Hartley, who came to the conclusion that the amount of protocatechuic acid in it was about 1 in 10,000, and certainly not more than 1 in 5,000. Such results furnished no explanation of the chief peculiarities of the urine, and, if correct, the subject was of little interest, scarcely calculated even to excite scientific curiosity.

Accordingly, we procured a specimen of pyrocatechin from Germany, and prepared some pure protacatechuic acid, from East Indian kino, according to the directions of Stenhouse, in Watt's *Dictionary*. We at once felt certain that we had a different substance to deal with, in our urine at all events, from either of these. Protocatechuic acid gave only a trifling brown color with alkalies, had no action on the copper test, and struck an intense deep green with ferric chloride in every proportion. We therefore cast about for another method of isolating the peculiar body in the urine in these cases, and at last hit upon one so simple and obvious, that the only wonder is it did not occur to previous inquirers, or earlier to ourselves.

This consisted in acidulating with hydrochloric acid, and shaking up with ether. By this process, an acid was at once set free, which proved nearly equally soluble in water and ether, and the behavior of which clearly showed it to be the immediate object of our search. It existed in large amount in the urine, and we found it could be extracted in abundance; from less than a week's urine we obtained from 200 to 300 grains of this acid. In doing so, we proceeded as follows: The urine was concentrated to a tenth or less, and was then washed with several volumes of ether to remove gummy and resinous bodies, which interfere with crystallization. Amongst the substances so removed was a yellow body, which also appeared to be peculiar to this kind of urine. The ether and the concentrated urine were next separated from each other, and the latter acidulated with dilute hydrochloric acid (one-half per cent. of the anhydrous acid to the original amount of urine). The urine was again shaken up with ether, when the new compound passed freely into it, communicating to it, at the same time, a yellow color, and from which it was afterwards deposited in a crystalline form.

Crystals could also be obtained without previous washing with ether, but of course mixed with some impurity. It was found that, if we acidulated and set free the acid before concentration, we could not afterwards obtain it by the ether, but only a product resulting from its decomposition. In this behavior, it resembles an acid which Schmiedeberg and Meyer obtained from the urine of dogs to which camphor had been administered, and to which they have given the name of glycuronic acid (*Zeitschr. für Physiol. Chem.*, B. iii., S. 422). If the acid were not liberated in the first instance, however, the urine might even be boiled down without producing any change in it. Another curious fact may here be noted. If the urine were acidulated and then shakenup with ether while still somewhat warm, much of the acid passed into a gelatinous state, and the whole tube might thus be filled with a jelly-like mass. This was also more readily produced by using large amounts of hydrochloric acid, and more strikingly still by the use of sulphuric acid. It was found that the acid might also be set free by acetic acid, but this required some time to act. This decomposi-

tion of the new acid during the evaporation of its watery solutions explains the failure of previous attempts to isolate it by precipitating first with neutral and then with basic lead acetate; decomposing the second precipitate by hydrosulphuric acid, and subsequently evaporating down. If, before, the latter procedure, we shook up with ether, we found that we could obtain the same crystals as by the other method, but in small amount, and not so pure.

The crystals formed on the evaporation of the ether assumed the form of large stellate groups, and sometimes also of sheaf-like bundles. On another and deeper watch-glass, they took the form of long thin prisms, with oblique ends. They possessed a strong aromatic odor, and a brown color, although in mass they seemed almost black, with shining colorless points or needles scattered here and there. They were very soluble in water and ether, but rather more so in the former, and the solutions were of a yellow color, becoming red, however, when sufficiently concentrated. We have not been able to identify this acid with any known to us, or of which we can find an account; and we would propose to call it, from its source and from its color, *urrhodinic* acid.

The crystals of urrhodinic acid thus obtained seemed tolerably pure; we could not detect any hippuric acid or other body amongst them, and a special search for the latter acid in the urine showed that it did not occur, if at all, in anything beyond mere traces. Three independent calculations proved that the urine contained one-half per cent., or a little more, of this new acid. A solution of this strength gave a reduction of the copper-test about the same as an equal quantity of the fresh urine, and produced the same depth of color with alkalies. In these two observations, the crystals had only been dried in the air, and still retained some moisture, so that the results must have been under and not over the mark. The amount of oxygen absorbed by 10 cubic centimetres of a half per cent. solution, in an alkaline condition, of crystals which had been dried over sulphuric acid, was found to be 8.2 cubic centimetres. Now the urine, of specific gravity 1019, had absorbed 10.2 cubic centimetres of oxygen, and therefore contained more than one-half per cent. of the urrhodonic acid. From the foregoing results, it will be seen that the acid has a reducing action on the copper-test about five times greater than an equal quantity of glucose, and this point was made the subject of a number of very careful determinations.

The crystals of urrhodinic acid were further characterized by the following properties and reactions:

1. In solution, they showed a decided acid reaction to test-paper, and gave all the reducing actions of Bödeker's alcapton and Ebstein and Müller's pyrocatechin, and which need not be here detailed.

2. When exposed to the air on watch-glasses, they absorbed moisture, and became viscid, but did not apparently undergo any further change. On recrystallizing from ether, however, after some lapse of time, the crystals were found to be yellower than before, and probably some alteration had been induced by the water they had absorbed. In watery solution, they spontaneously decomposed, gradually in the cold, but more rapidly if boiled, depositing a dark powder, and leaving still something in solution, which was unaffected by further boiling, which did not crystallize, or only very imperfectly, and which still exercised a marked action on the alkaline cupric oxide solution. The dark powder was insoluble in water, alcohol, and ether, but dissolved in alkalies, and turned the copper solution green, but without reduction.

3. An ethereal solution, so strong as to have a bright red color, did not appear to undergo any change, though exposed to light for months; but, on evaporating the ether, crystals were not deposited as before, but an amorphous mass, apparently a mixture of a yellow and a brown substance. The latter only was now found to be affected like the original acid by alkalies; and, after being made alkaline, the yellow could be readily removed by ether. It was deposited in little yellow masses, and radiating lines with a remarkably silky appearance, and of a beautiful canary-yellow. This body, which for convenience we may call serixanthin (σηρικός, silken), was neutral in reaction; very soluble in ether, but more sparingly in water; was unaffected by alkalies, and had no action on Fehling's solution beyond turning it green. The brown has not yet been obtained apart from the yellow; the solution of both together was more yellow than that of the original acid, was of acid reaction, darkened as before with alkalies, and reduced cupric oxide.

4. The crystals formed somewhat pasty cakes when left on watch glasses exposed to the air; over sulphuric acid these became thin scaly plates of a brown color, but with glistening points scattered over the surface. When pulverized in a dry mortar, a dull, earthy-looking powder was formed, and this

melted at 180–185° Fahr. (82–85° Cent.) to a dark, viscid, treacly, almost tarry mass, evolving at the same time a fæcal odor. The mass boiled about 260° Fahr. (126.6° Cent.) and boiled steadily for some time at 264° Fahr. (128.8° Cent.). It then fell gradually, still boiling, to 248° Fahr. (120 Cent.), after which it rose again, and on continuing the application of heat till the temperature rase to 400° Fahr. (204.4° Cent.) and upwards, carbonic acid was given off, and the fæcal odor already mentioned became very powerful. Some of the crystals were strongly heated in a crucible, and the fæcal odor thus developed was overpowering. Bödeker's alcapton, though *ohne Geruch und besonderen Geschmack*, evolved, when heated on platinum foil, an excessively disagreeable, penetrating odor, reminding him of biliary substances. From the dark, half-charred residue, ethereal and watery extracts were obtained, which we found to yield crystals on evaporation. Ether extracted a compound to which a good deal of foul odor clung: and which crystallized in little pyramids and small radiating or stellate forms. These were brownish, dissolved very freely in ether, but sparingly in water; the watery solution was neutral, and even when apparently very weak gave a deep green and then a brown with alkalies, and exercised a strong reducing action on Fehling's solution. We obtained a watery extract which deposited large, irregular red crystals; a deep, almost coppery red solution of these, evaporated in a steam bath, left a deposit showing all the colors of the spectrum in concentric circles.

5. The behavior of urrhodinic acid with ferric chloride was peculiar. When to a solution sufficiently strong to have a tinge of color a weak solution of the chloride was cautiously added without agitation, a distinct but not very deep green was perceived, apparently belonging to a precipitate and not in solution, but this almost immediately disappeared, no matter what the proportion of the constituents of the mixture. If the solution of the acid was so strong as to be reddish-brown, the precipitate was dark, as if brownish-black, and a coppery color was developed before its disappearance.

6. The acid gave beautiful white precipitates with both neutral and basic lead acetate.

7. On platinium-foil the crystals burned with a luminous, somewhat smoky flame, leaving a small residue of charcoal, which was more slowly but completely consumed.

8. Heated with soda-lime, no ammonia was evolved. The compound was therefore free from nitrogen.

It is unnecessary to give further reactions. We have not yet made an ultimate organic analysis of this body, but have everything now in hand for doing so.

We have already stated that a peculiar yellow body may be extracted by ether from this urine without acidulation. This crystallizes with some difficulty in wavy and branching forms. It is of neutral reaction, not affected by alkalies, and only turns Fehling's solution of a green color. Without certain precautions, it is obtained along with a small admixture of the compound which yields the urrhodinic acid, and this mixture gives first a green and then a brown with alkalies, and is unquestionably the supposed pyrocatechin of Ebstein and Müller. This yellow body is probably itself a decomposition-product of urrhodinic acid, but the crystalline form is not the same as that of the serixanthine already mentioned.

It would appear as if all the peculiarities of this urine were not explained, even by the presence in it of so remarkable a body as urrhodinic acid. The low amount of urea, and apparently of the other nitrogenous compounds of normal urine, seems to forbid such a conclusion. The further we proceed in the matter, we feel the more certainty in stating that this urine contains some nitrogenous compound peculiar to itself, and of which the urrhodinic acid is a decomposition-product. By a certain method of extraction, we have, in fact, obtained a body which yields a large amount of urrhodinic acid by acidulation, and which, when heated with soda-lime, evolves ammonia in abundance. We believe this compound was not altogether free from impurity, but feel sure that it could not contain so much of a nitrogenous nature as to yield the large amount of ammonia given off. We are repeating this process with further precautions against error from this source.

It is interesting to observe that the urine in the case published by Schmiedeberg and Meyer also contained a nitrogenous compound which they believed to be a uramido-campho-glycuronic acid. The kind of urine we have been considering must result from a profound perversion or arrest of the metabolic processes, and its further investigation may throw fresh light on some important problems, as that of the antecedents of urea and others.*

*We have examined human urine in many diseases, and the urine of the horse and cow in a few instances, but have not found any trace of urrhodinic acid.

Sounding the Frontal Sinus.

In the *Berliner Klin. Wochensch.*, No. 3, 1887, is a paper on this procedure, which has hitherto been thought impracticable. Ph. Schech in his work says that he failed to pass a sound from the nasal cavity into the frontal sinus "after repeated attempts;" and C. Michel believed that it would be necessary first to remove the middle turbinated bone. It will be remembered that the opening from the middle meatus into the frontal sinus is only diminished by the mucous membrane, not entirely closed. Jurasz's first attempt was made four years ago in a case of purulent catarrh of the frontal sinus and temporary retention of the secretion. The following is a short abstract of this case, which was narrated at Freiburg in 1883 (Laryngological Section): A servant girl, aged 17, attended among the out-patients on December 18, 1882, complaining of severe frontal headache. There was an abundant purulent discharge from the nostrils, and whenever this discharge diminished, the pains increased, and *vice versa*. After galvano-caustic removal of the hypertrophied part of the middle turbinated bone, the nasal cavity was douched three times daily, and various means were used in addition—insufflations of boracic acid and various astringents—all without effect. On February 4 the first attempt to pass the sound was made. A fine thin metal probe was introduced into the right middle meatus and pushed gently forwards, when engaged in the aperture, to the frontal sinus; measurement showed that the sound must have passed into this. No pain was given, though a few drops of blood escaped with the pus. The patient soon felt better, and the probing was repeated once or twice a week, with great relief, not only on the right, but the left side. The final result, however, could not be stated, as the patient soon left Heidelberg. So far there was no proof of the actual passage of the sound; but in July, 1883, there was brought to the notice of Prof. Jurasz a patient whose frontal sinus was fully laid open by a cancerous ulceration of the forehead. The dressings were not at once removed, but the sound was first passed from the left middle meatus, and then, on removing the dressings, the end of the probe was plainly visible in the frontal sinus, being freely movable therein. Dr. Kilian, of Worms, a specialist, was present at the time, besides others; but in this case the probe could not be passed from the right side till three attempts had been made, the opening being oblique. Since then this probing has been tried in twenty-one cases more, principally for catarrh of the frontal sinus. In five cases this was done equally on either side, and without trouble; in six great difficulty was encountered (and finally overcome) on one or both sides; and in ten the attempt had to be abandoned. In all these cases the aperture into the frontal sinus could be distinctly seen; other cases in which, from new growths or swelling of the mucous membrane, or deviation of the septum, that opening could not be seen, are not reckoned here. Thus the percentage of successful operations is as yet but small, but may be increased. Metal probes very fine and slightly knobbed were used; but perhaps whalebone would be a better material. A handle is unnecessary. The difficulties vary; the ostium frontale may even be absent on one side, or there may be more than one opening. In any case the anterior part of the infundibulum is the site of the opening, if present, where there is a comma-shaped rim rounded off upwards, when the head is thrown back. This is the place to aim at. The length of the bony canal is twelve to sixteen millimetres, and its lumen is not uniform. Its direction, too, may be either outwards or inwards, and may even be angular. The probe must be moved forwards lightly and carefully, otherwise the mucous membrane may be injured, and the sound be entangled in a false passage. The chief indication for this procedure is purulent catarrh of the frontal sinus, when the secretion is pent within and cannot escape. The case narrated shows the good consequences of this operation, which may thus prove an acceptable substitute to the usual puncture of the sinus from the nasal cavity by a trocar, or the occasional trephining from without.

Case of Undue Frequency of the Pulse.

Before an English medical society, Dr. Blaikie Smith read notes of a case where this was the only apparent deviation from health. The patient, a blacksmith, aged 54, was admitted into the infirmary on March 1, complaining of an uneasy feeling over the præcordia, and shortness of breath on exertion. The apex-beat was invisible, and could not be felt; slight heaving was felt over the epigastrium, but no other pulsation. Auscultation showed the heart's action to be 196 per minute; the sounds were like those of the fœtal heart, and there was no murmur. The heart was not enlarged; the pulse was regular, but feeble and compressible, and its beats corresponded with those of the heart. The lungs were healthy; there

were no abdominal symptoms; the urine was normal, and there was no dropsy. Save that for several years he had suffered occasionally and without evident cause from attacks of beating and jerking over his heart, the previous history was unimportant. Shortness of breath and sometimes perspiration attended these attacks, and they subsided abruptly. The present attack came on several days before his admission. Bearing in mind that attacks of undue frequency of the pulse sometimes end spontaneously, the case was simply watched for twenty-four hours. The pulse-rate was then still unchanged, 196 per minute, and the sphygmograph gave a hyperdicrotic pulse-tracing. With the view of lowering the pulse-rate and increasing its tension, tincture of strophanthus (1 in 20) in five-minim doses was ordered to be given every four hours until the pulse-rate was reduced, the quantity of urine being measured. On March 3, after three doses of strophanthus, the pulse was 200, regular, and could be counted only by auscultation of the heart and timing with a watch. Sphygmographic tracing showed the pulse to be of still lower tension and feebler character than on the day before; urine 100 ounces. On March 4, after eight doses of strophanthus, the pulse was 64, natural. Sphygmographic tracing showed a regular pulse, with very characteristic marks of high tension. The heart's action and sounds were normal; the apex-beat was in its usual situation. One hundred and five ounces of urine were passed, and the patient felt well. From that date till he left the hospital on March 8, nothing further worthy of record occurred. The pulse rose to 80, the sphygmographic tracing became more natural, and the urine fell to the usual amount. Dr. Smith considered that the treatment had conduced to the relief of the symptoms on account of the remarkable changes in the pulse-tracing, and the concurrent increase in the secretion of urine. Dr. Smith had hoped to confirm his opinion by further observation in similar attacks, but the patient, probably alarmed at the frequent use of the sphygmograph, levanted from the hospital before this could be attained.

Washing Out the Stomach in a Case of Intestinal Occlusion.

In a communication to the Clinical Society of Paris, M. Jacos relates the following case, a summary of which appears in No. 7 of *La France Medicale:*

B. Valentine, æt. 26, was admitted to the Hotel Dieu under the care of M. Empis, on the 17th of March, 1886. B. is three months pregnant, and is stout in build. She states that on the 14th instant she was suddenly seized with a severe fit of vomiting unaccompanied by pain. In the evening of the same day she vomited several times again; after ten hours she began to feel pain in the abdomen. The vomit was a yellowish fluid; and pain now became more marked in the abdomen. During the next two days she was unable to keep down any nourishment, and her urine was very scanty. On admission to hospital, her eyes were sunken; the abdomen was distended and tender to pressure, and the form of a pregnant uterus was easily made out by manipulation. Nothing was learned from a rectal examination. The hernial orifices were free. From the 18th to the 22d, her condition was miserable; no action of the bowels; the abdomen greatly distended; urine very scanty; and the yellowish non-feculent vomit continuing without cessation. On the 22d she became very restless. The tympany increased, with considerable dyspnœa and a continuance of the vomiting. Injections produced no result; 40 grammes of eau de vie were given.

23d. The same injection as yesterday, without result. The patient sinking.

24th. The general state of the patient worse. Pulse small, temperature 97°; tympany very severe; suppression of urine; vomiting non-feculent but continuous. First washing: Two litres of very cold water (kept cold by ice) were introduced into the stomach, but were quickly returned, as clear as when introduced. It was noticed that on the introduction of the water, the patient complained of a very violent pain in the stomach. No vomiting occurred that evening, and the patient appeared greatly relieved, and passed about 200 grammes of urine. Ice applied over the abdomen.

25th. Vomited once to-day; during the night complained of violent pains in the abdomen, and passed some wind per anum. Second washing out of stomach as yesterday with ice-cold water, followed by similar pains to those of yesterday. During the evening of the day she passed a very liquid stool, with much wind.

26th. The more alarming symptoms have disappeared, so it was deemed unnecessary to again wash out the stomach.

On the 27th she was discharged cured, and her health remained good during her confinement at the normal period.

In the discussion that followed the reading of the paper, the question came up as to how the

washing out acted, some holding the opinion that poisonous products were washed out; others, that the cold fluid by causing contraction of the viscus, excited a peristaltic movement. Considering the apparently hopeless case that was so quickly cured, the remedy is one well worth trying before operative procedures are resorted to in cases of intestinal occlusion.

The Cause of Chronic Gastric Ulcer.

The pathology of chronic ulcer of the stomach, in spite of the great mass of clinical and anatomical facts collected, remains unsolved. The usually accepted theory as to its cause is that it is the result of self-digestion by the stomach over an area of mucous membrane the vessels of which have been blocked by embolism or thrombosis. This theory is very plausible in appearance, though no facts directly tending to establish it have been discovered. Rasmussen, of Copenhagen, has lately suggested another theory, which he considers will explain many cases of ulceration of the stomach. It is, for example, not uncommon to find, after death, a groove on the stomach extending from about the middle of the lesser curvature obliquely towards the greater curvature. This groove is often marked by a distinct thickening of the serous membrane, and may be continuous with a similar groove on the liver. In some cases the mucous membrane beneath the sulcus is atrophied; in others it is normal, and lies in folds. The groove of the stomach takes the direction of the left ribs, and is caused by pressure on the organ through tight-lacing. Rasmussen compares the number of cases where this groove is found with the number of scars of ulcers in actual ulcers found in the cases. In the hospital from which the cases are taken, and which is reserved for the incurable and the aged poor, he finds scars, representing old ulcers of the stomach, in seven per cent. in men and thirty-two to thirty-six per cent. in women over forty years of age, the majority of the scars being in the same position as the groove caused by pressure. A closer examination of many cases showed that the groove of pressure was present, and was accompanied by a scar of the mucous membrane lying underneath. Rasmussen further states that if tight lacing be considered the cause of ulcer of the stomach, it is readily understood why the scars observed *post-mortem* are often symmetrical on each side of the lesser curvature, why they are more numerous on the posterior surface of the organ, and why they are usually about the middle of the lesser curvature. Ulcer of the stomach, according to this idea, would therefore be considered as a pressure necrosis.

Electricity in Epilepsy.

Dr. A. D. Rockwell thus concludes a paper in the *N. Y. Med. Jour.:*

1. Electricity possesses a certain value in the treatment of epilepsy. It is not known, nor is it alleged, that used alone it can cure epilepsy. Used in connection with the bromides, however, its value is unmistakable, and under its use a certain proportion of patients will recover that otherwise would fail to do so.

2. It is in the nocturnal variety of epilepsy more especially that the good effects of electricity are seen, although day attacks have been successfully controlled.

3. The methods of electrical treatment that have proved most efficacious in my hands are central galvanization and general faradization.

4. When electricity fails to cure, or aid in the cure, it is often efficacious, by the method of general faradization, in affording grateful relief from nervous symptoms of an indefinable subjective character; in other words, from that general instability of the nervous system recognized under the term neurasthenia.

5. The systematic use of electricity renders the system more tolerant of the bromides, and will diminish bromic acne.

6. It is important that electrical treatment should be administered with care and judgment; especially should all interruptions of the current be avoided in central galvanization, as the resultant shock is liable to hasten rather than prevent an attack.

7. Two years must elapse without any attack before any case of epilepsy can be considered as one of positive cure.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The 68th Annual Report of the New York Institution for the Instruction of the Deaf and Dumb, which we have received from Dr. F. C. Riley, shows how admirably that beneficent charity is managed, and how valuable are its services to the afflicted under its care.

——In a reprint just received, the eminent laryngologist, Mr. Lennox Browne, F. R. C. S., describes a successful case of partial excision of the larynx on account of intra-laryngeal epithelioma.

——The annual address before the American Academy of Medicine last fall was by Dr. R. S. Sutton, his subject being "Medical Education in the United States, its Defects, and the Remedy." The address is now issued in pamphlet form, and is a thoughtful production.

——The Long Island College Hospital of Brooklyn issues its 29th annual announcement in unusually attractive form, and with an ample amount of matter.

——The Medical Jurisprudence Society of Philadelphia have published a paper by Walter E. Rex, Esq., entitled "Will Contests." It is a valuable resumé of customs and decisions upon this important subject.

——Dr. C. H. Hughes of St. Louis, in a paper before us, maintains the curability of epilepsy and allied affections by galvanism and the phosphated and arseniated bromides.

BOOK NOTICES.

The Practitioner's Hand-book of Treatment, or, The Principles of Therapeutics. By J. Milner Fothergill, M. D., etc. Third American edition. Cloth, 8vo., pp. 660. Philadelphia: Lea Bros. & Co., 1887.

In writing this treatise, Dr. Fothergill undertook to approach the subject of therapeutics in a new and more philosophical manner than previous authors. Taking up one after another each of the great processes which are the conditions of the existence of organic life in man—such as assimilation, excretion, respiration, reproduction, etc.—its physiology is first explained, and then the interferences with it are considered, which leads to an examination of the action of remedial agents, and finally to their clinical application.

This scheme is excellent, and that Dr. Fothergill has been enabled to meet the expectation of readers in the management of it seems shown by the sale of several editions of his work, both in this country and in England.

To the present edition he adds two chapters, one on "The Dietary in Acute Diseases and Malassimilation." and another on "The Management of Convalescence," while the whole of the text undergoes a careful revision.

Medical Electricity; a Practical Treatise on the Applications of Electricity to Medicine and Surgery. By Roberts Barthoolow, A. M., M. D., etc. Third edition. Illustrated. Cloth, 8vo., pp. 304. Philadelphia, Lea Bros. & Co., 1887.

The third edition of this work has been prepared by its author with his usual careful research into medical literature. The additions, he states, fall chiefly within the therapeutic sections, and a fuller account has been given of the appliances for electrical illumination, for electrical baths, and for galvano-cautery.

The volume is in moderate compass, and contains a brief exposition of the general topics of electro-physics, electro-diagnosis, and electro-therapeutics, including the applications of the agent to surgery. The author congratulates the profession on the growth of the appreciation of electricity as a remedial agent. He thinks that to utilize it in practice is now a commercial necessity for every physician, and is entirely confident that the time has now come when we may claim for it positive therapeutic results.

The Medical Student's Essentials of Physics and Chemistry. By C. W. Cutler, M. D. Second edition. 12mo. J. H. Vail & Co., N. Y., 1887.

This is a small, well-arranged, carefully-prepared book for the use of students of medicine, and will no doubt be welcomed by many to whom these branches are particularly dry and difficult.

Treatment of Typhoid with Quinine.

At a recent meeting of the Academie de Médecine, M. Dujardin read a paper on the treatment of typhoid fever by quinine and warm baths. The quinine is administered every day in divided doses, of which the total would be about twenty grains. During the first week powdered digitalis is given (four grains daily), and the warm baths are used morning, noon, and evening, the patient remaining therein about 20 minutes each time. The author of the communication, a doctor from Montpellier, assures that out of sixty-five cases thus treated he had only one failure. M. Dujardin, in commenting upon the paper, while encouraging his confrere, thought that we shall never be able to understand the real treatment of typhoid fever until the microbe be better known and cultivated.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

BRIGHT'S DISEASE WITHOUT ALBUMINURIA.

According to Dieulafoy (*Semaine Medicale*, March 16, 1887), as there are now and then cases of albuminuria without nephritis ("transient" or "physiological albuminuria"), so Bright's disease may run its course without a trace of albumen in the urine, or with the presence only exceptionally of this proximate principle in that excretion. This is a fact which is generally admitted in its application to the contracted kidney. In cases, then, where albumen is persistently absent in the urine, the diagnosis of nephritis must be made by the help of other semeiological indications, such as headache, visual troubles, deafness, hypersecretion of urine, "dead fingers" increased sensitiveness to cold, pruritus, dyspeptic troubles, dyspnœa, etc., which will often give a hint as to the true nature of the malady, with or without the convulsive, comatose, and delirious manifestations which characterize the uremia of clinical observers.

Dieulafoy advances three orders of proofs —clinical, experimental, and anatomical.

1. Clinical observation teaches that at the onset of certain cases of chronic nephritis, there may be entire absence of albumen in the urine for a long time; this it is which Mohamed has called the *pre-albuminuric period of Bright's disease*, a denomination which Dieulafoi does not accept, as many well marked cases of Bright's disease have been observed by him where throughout the disease, at the end as well as at the beginning, the urine was free from albumen, and yet the autopsy disclosed the lesions of chronic nephritis. He reports several cases which present great interest in this connection; we have room for only one.

A woman entered St. Antoine Hospital, May, 1886, for a violent cephalalgia. Four years before, without appreciable cause, she had been taken with anasarca of the extremities. At this period she was suffering from headaches, pains in the loins, painful cramps in the legs, and asthmatic breathing. This group of symptoms led Dieulafoi to suspect the existence of acute nephritis. At the end of three months there was improvement in all these symptoms, although the patient was subject to frequent headaches; this state of relative health lasted two years, when the patient found that she could no longer hear well; the headaches became more violent and more persistent, while the pains in the loins, the paroxysms of dyspnœa with precardiac distress, returned. At the time of her entrance into the hospital, the headaches and cramps were very severe, the legs were

œdematous, there were noises in the ears, motes before the eyes, and a marked sensitiveness to cold, especially in the evening. Auscultation of the lungs revealed a healthy state of these organs, but there was a *bruit de galop* (a very important diagnostic sign, according to Potain,) over the heart. Dieulafoi made the diagnosis of Bright's disease of four years' date; and nevertheless the urine examined for twenty-six consecutive days never gave a trace of albumen, while urea and the potash salts were in less than normal amount. The autopsy showed the diagnosis to be correct.

2. The experimental proof consists in the ascertainment by chemical analysis and otherwise of the diminution of urea secretion. A good way to determine the lessened toxicity of the urine by reason of diminution of its nitrogenous waste, is to note the result of the injection of a certain quantity in the veins of some animal, as the hare. With normal urine, it is necessary to inject 50 grms. for every kilogramme of the animal's weight in order to kill the animal. Thus if the animal be a hare weighing two kilogrammes, the quantity necessary to produce death will be 100 grms. of urine. In the pathological state, however, where from atrophy of the glomerules, or other cause, impeding or suppressing their function, the waste matters are much less than in the normal state, it takes a much larger quantity of urine when injected into the veins of the animal to kill it; 100 grms., and even more, per kilogramme, will fail to have a decided toxic action; sometimes such urine seems to be almost as harmless as water.

In the case of the patient whose history we have just sketched, Dieulafoi found that he could inject with impunity in a hare of two kilogrammes weight, 230 grms. of urine without any toxic results, excepting a little dyspnœa and the rather profuse diuresis and some diarrhœa which followed. An injection of 100 grms. of normal urine, says Dieulafoi, would infallably have killed this animal.

3. The patho-anatomical proofs are such as the autopsy furnishes in confirmation of the diagnosis made by a careful estimate of the pathognomonic symptoms of the disease, albuminuria only being wanting. It is worthy of note that in the cases reported by this writer, the lesions noted were those of *the small contracted kidney* with arterio-sclerosis, and marked wasting of the cortical substance. It has long been known that in this form of Bright's disease, which is frequently unattended with dropsical effusions (sometimes there is only a slight œdema about the ankles in the last stages), the absence of any considerable amount of albumen in the urine is rather the rule than the exception.

Notes and Comments.

Poisoned by Bichloride of Mercury.

What enormous quantities of corroding poisons may occasionally be taken without directly endangering life, is shown by the history of two cases reported in the *Deutsche Med. Woch.*, 12, 1887, by Dr. Hildebrandt. In both cases, by mistake, instead of a morphine powder the patient swallowed sixteen grains of corrosive sublimate. Happily emesis rapidly occurred, and the accident being promptly discovered, large quantities of the white of an egg, dissolved in water and opium, were at once administered. In both cases recovery was complete and rapid. There was no indication of a profound destruction of the primæ viæ—as should have been expected from the effect of so large a dose of a corroding poison.

The cases are instructive, but if Dr. Hildebrandt at the conclusion declares "our fear of corrosive sublimate" as exaggerated, we must confess we cannot understand him. Does the fact of the two cases having survived at all prove the non-corroding character or the innocuous nature of the bichloride? It is well known that enormous quantities of the most virulent poisons have at times been swallowed without their having caused any ill-effects whatever. These cases are easily explained, for almost all poisons, when taken in too large a quantity, at once act as an emetic, and many a would-be suicide has to thank for the preservation of his life, his ignorance of the dose of poison needed to induce death. They wish to make assurance doubly sure, and take too much. Further, the prompt administration of the proper antidotes, especially if at once given in those cases where the swallowing of the intoxicating substance was immediately followed by vomiting, has saved lives over and over again. Many experiments have been made on animals, showing the value and importance of early action. Only recently the Medical and Surgical Reporter published the experiments of a German investigator, who immediately after administering fatal doses of various poisons—aconite, strychnine, alcoholic—had completely neutralized their effect, and therefore totally

prevented all evil consequences, by at once applying the proper antidote, which in the cases referred to consisted in injecting into the circulation an indifferent fluid corresponding in quantity to 8 per cent. of the bodily weight of the animal experimented upon. The same has often been done with physiological antidotes.

That the two cases reported by Hildebrandt survived cannot surprise, therefore; but we must wonder at the conclusion of the doctor, who believes himself justified in drawing the inference that corrosive sublimate is not as corroding nor as virulent as is generally supposed. We question whether Dr. H. would be willing to swallow two grains of the bichloride, to test its innocuous character and non-corroding action. We would advise him in such a case at once to adopt the same procedure which proved so successful in his own two cases, otherwise he might never live long enough to tell the tale.

Such statements as that of Dr. H. concerning the action of a poison well known to be one of the most virulent and corroding of all mineral poisons, can only lead to mischief. No matter how many persons may preserve their lives notwithstanding their swallowing large doses of the corrosive sublimate—either because of the latter, or on account of the prompt application of antidotes—the fact will always remain undisputed, that the drug is a highly poisonous substance, which should invariably be used with the utmost care. Its action must be watched, even when applied externally to ulcerating or suppurating surfaces, or to wounds of any kind, Many cases have been reported but recently where the prolonged application of the bichloride to a wound produced alarming symptoms of poisoning. *Sapienti sat!*

The Treatment of Tonsillitis.

In the *Journal* of January 3, 1885, Dr. G. Partagas recommends the local application of bicarbonate of soda in tonsillitis "before the pain of swallowing is excessive." "Since that date I have tried (says Dr. W. J. Baker, *Brit. Med. Jour.*,) this treatment in a large number of cases, and have invariably found it give great relief, not only in the early stages of the disease, but also when suppuration seemed inevitable. Many patients who were quite unable to swallow even liquids without acute suffering were, in the course of an hour or two, almost entirely free from pain, and in the course of four or five days the disease was cured. I advise the patient, having moistened the tip of the index finger, to dip it into the powder and then rub it gently all over the tonsil; to repeat this every five minutes for half an hour, and then once every hour for the rest of the day. After that two or three applications a day are sufficient until the inflammation has subsided. Since I commenced this treatment, I have never yet had to incise an inflamed tonsil. In one case where suppuration was manifest, the abscess burst under pressure of the finger. The last case I treated was a young soldier just out from home who was suffering from follicular tonsillitis of both glands, with gray patches of exudation, accompanied by a certain amount of fever. He was discharged cured in four days. I can strongly recommend all who have not yet used this treatment to give it a trial."

Inhalations of Carbolic Acid in Whooping-Cough.

About a year ago, Dr. R. Pick published the results which he had obtained from the inhalations of creasote by the aid of an apparatus which, while confining the vapor to the air-passages, allows the entrance of the atmosphere. This apparatus, which has the character of a mask, was described in the MED. AND SURG. REPORTER. Dr. Pick has next tried the effect of the inhalation of pure liquefied carbolic acid in whooping-cough (*Deutsche Med. Woch.*, 12, 1887). He places into the apparatus a small ball of cotton-wadding, into the centre of which 15 drops of the carbolic acid are poured. The mask is then worn the whole day, or at least for six hours consecutively. About three times daily the cotton ball is replaced by a fresh one. For the purpose of early discovering any possible intoxication, the urine was examined every day. Dr. P. records the results which he obtained by this method in five children as follows:

1. The course of the whooping-cough becomes much milder, and is decidedly shortened.

2. Notwithstanding the prolonged application, no symptoms of poisoning made their appearance.

The latter point is important, as Dr. A. Schmitz not long since reported the occurrence of convulsions after the inhalation of carbolic acid gas.

Degeneration of the Cortex.

All parenchymatous encephalites, no matter what their direct result, can never be

considered completely cured, unless the individual has been for years under observation and given no signs of disturbance of the functions of the brain. It seems as if these inflammations are apt to give rise to a peculiar degenerative process in the convolutions of the brain, and the longer the inflammation, and therefore the disturbance in the nutrition of the parts continues, the greater appears to be the danger of fatal consequences, which may develop years later.

These cases are rare, and one observed by Dr. Hess (*Wiener. Med. Jahrb.*, 1887, p. 211,) is therefore of great interest. A woman, æt. 67, had suffered when 31 years old from a parenchymatous encephalitis. She was seized, a year before her death, by several apoplectic attacks, became finally palsied on the right side, and showed diminution of intelligence in general. The autopsy revealed a peculiar degeneration in the cortex of the cerebrum, the surface was uneven and hard at places, and disseminated hollow spaces of irregular shape and of various sizes, empty or filled with areolar tissue and fibres, were met with, all evidences of some chronic degeneration going on for years. In the cerebellum one single larger focus was met with. H. observes that the few cases recorded in literature, where the post-mortem gave the same result, all had a previous history of a parenchymatous encephalitis years before the outbreak of the final disease.

Cæsarian Operation and Chromic Acid—Catgut.

Dr. Mikulicz recommended some time ago the employment of catgut ligatures, which have been previously soaked in a strong solution of chromic acid. Dr. Leopold, who was in the habit of using silver sutures in his operations within the abdominal cavity, has recently tried the catgut treated as recommended by Mikulicz (*Deut. Med. Woch.*, 21, 1887). A woman with a pelvis rachitic in a high degree with a conj. vera of 6½ ctm., and another with a pelvis in a similar condition, but the diameter only 5¾ ctm., had the Cæsarian operation performed on them by L. In the first case 10, in the latter 12 deep chromic acid catgut sutures were applied. The catgut remained in an excellent state throughout, and L. ascribes the remarkably good result, which he obtained in both cases, to these catgut ligatures. They do not yield, and thus prevent hemorrhages with all their usual septic consequences; and neither are they absorbed too early. The catguts are prepared as follows: Raw catgut is placed for 48 hours in 10 per cent. carbol-glycerin, afterwards it remains for five hours in a solution of chromic acid of one-half per cent., and it is finally preserved in absolute alcohol. This preparation, while possessing all the advantages of the common catgut, has none of its drawbacks.

Symptoms of Poisoning After Balsam of Indian Hemp.

Dr. A. Miller, in Munich (*Munich Med. Woch.*, 11, 1887), prescribed for a vigorous peasant woman, who had been suffering for some time with insomnia, the balsam of Indian hemp, as recommended by Dr. Jul. Danzel. The first pill, containing only about 1½ grains of the balsam (0.10) produced a semi-comatose state, all kinds of anomalies of sensation, very great dryness in throat and pharynx, feeling of fainting, and hallucinations. The pulse was 120, threadlike. About one hour after the second pill, and after the administration of strong black coffee, emesis occurred, and both pills were vomited very little changed.

M. has observed similar symptoms of intoxication in restless patients, to whom he administered the balsam of Indian hemp. The dose in these cases always averaged about five grains (0.3). Especially in two cases, one with an organic heart and kidney disease, the other tuberculous, where the usual hypnotics had been of no avail, the dose of the balsam could not be repeated on account of the grave symptoms developing.

The balsam of Indian hemp, which has been greatly praised by many observers, evidently is far more active in its effect than the extract, and caution is needed in its use.

Treatment of Hepatic Abscess.

At a recent meeting of the Académie de Médecine, M. Rochard reported a case of hepatic abscess which had been communicated by MM. Ferron and Coustan. He remarked that since the expeditions to Tonquin, Madagascar, and Senegal, many fatal cases of abscess of the liver had occurred which might have been eured had they been recognized and operated on in time. The case reported by MM. Ferron and Coustan had done well, as it had been operated upon when the abscess threatened to burst into the pleural cavity. Accordingto M. Rochard, the best way of treating abscess of the liver is by free incision, washing out the cavity with an antiseptic fluid, and drainage, the wound being dressed after

Lister's method. As soon as a purulent collection in the liver is discovered, prompt action should be taken. M. Trelat agreed with M. Rochard, and remarked that the operation in question was performed every day in the hospitals of Paris. Abscesses of the liver might be opened if there were no adhesions, and if care were taken to unite the edges of the wound in the liver with the edges of the skin wound. The danger of simple puncture arose from the fact that it was not aseptic.

Fatal Result of Large Doses of Thallin.

Professor Ehrlich, who has had very good results from thallin in typhoid fever, has had the candor to report a case (*Münchener Med. Wochenschr.*, No. viii.,) which ended fatally under repeated progressive doses; namely, 0.08 up to 0.58 grammes (one and a quarter grains to nine grains nearly)—of thallin tartrate. The necropsy showed the lesions of typhoid fever in the healing stage, cardiac hypertrophy and dilatation, fresh mitral endocarditis, and hemorrhagic infarcts in the renal papillæ, the last-mentioned being, as shown by experiment, a characteristic sign of thallin poisoning. Ehrlich assumes that the cardiac condition caused defective excretion and consequent accumulation of thallin. The danger may be completely avoided by fixing as the maximum dose for hourly administration 0.2 grams of the tartrate (3 grains). In the progressive administration of thallin, very small doses are used at first—namely, 0.07 or 0.08 grammes—and this amount is increased daily by $\frac{1}{100}$ gramme. Heart-failure of any kind is a contra-indication of thallin treatment; so are the various forms of kidney disease, and also cases which resist the influence of small doses.

Constipation.

Whether constipation (says the *Med. Press*), is a symptom or a disease, or whether it may not be found in both categories, we do not now propose investigating. All who have read Abernethy's lectures know how much stress he placed on not allowing feces to accumulate in the colon. In 1883, O'Beirne issued his "New Views on Defecation," which he dedicated to the then Lord Lieutenant. The book has now few readers, but the lessons it conveys are well worthy of reproduction. We are led to these considerations by a very valuable paper in the *Medical Bulletin* of Philadelphia, by Dr. J. S. Jewell, on the evils of constipation; and we cannot help thinking that many young practitioners would find a greater success attendant on their efforts, if they devoted more attention to the commoner complaints of humanity. The pain in the side, the languor, headache, pasty countenance, and cold feet, are more readily got rid of by a simple purge than many recently qualified physicians imagine. No physician can be too well educated, but we confess that he succeeds best in his professional career who is most intimate with the every-day troubles that afflict mankind.

Cerebral Localization.

The following two cases occurred in the practice of Dr. Salessis (*Encephale*, '87, 3):

Female child, æt. 16 months, general convulsions followed by right hemiplegia with contractures. When æt. 15, grave epileptic attacks with inter-current periods of excitement of an erotic character. Death from phthisis.

Autopsy.—Atrophy in a high degree of the whole left frontal lobe and of both central convolutions, and signs of degeneration in their deeper course.

A man, æt. 32, suffering from general progressive paralysis. Nineteen years before, amputation of the right arm.

Autopsy.—Atrophy of the upper part of the left anterior central convolution.

Whenever convulsions are accompanied by symptoms of paralysis with no other indications of cerebral disturbance, the disease always resides in the gray tissue of the cortex, and in most cases is limited to the anterior lobe, though occasionally also in the motor area of the ascending parietal convolution.

Prevention of Epileptic Fits.

Thinking the following treatment for cutting short and aborting an epileptic fit might be of interest, Dr. F. W. Devereux Long records it in the *Brit. Med. Jour.:*

"A lady, aged 23, has been under my care for nearly two years, suffering from epilepsy, which began about five years ago, she attributing it to a knock on the head from a plank a man was carrying. These fits are both of the *petit mal* and *haut mal* varieties, aud were very frequent when she first came under my observation, but she can nearly always make them abort by taking a draught of cold water when at hand; not always having it within reach, she requested me to give her something she could carry about

with her. I gave her some nitrite of amyl globules, five minims in each, and directed her to break one in her pocket-handkerchief and inhale it when she felt an aura. This remedy she has seldom found to fail, and moreover it frequently cuts short a fit, especially in the first stage. I have frequently found this remedy useful in similar cases."

Biniodide of Mercury as an Antiseptic.

Dr. P. K. Bolshesolsky, of St. Petersburg (*Vratch*, No. xi., 1887, p. 220), from numerous experiments made by himself in Professor A. P. Dobroslavin's laboratory, concludes that biniodide of mercury is a more powerful and less poisonous antiseptic than corrosive sublimate. Thus he fully confirms the observations of Bernhardy. A solution of 1 in 4,000 destroys putrefaction microbes more completely than a sublimate solution of 1 in 2,000. The biniodide dissolved in a solution of iodide of potassium was recently tried with apparently good results in three cases of laparotomy, under Professor A. I. Krassowski. For washing the floor, a solution of 1 in 4,000 was employed; for disinfecting the hands, 1 in 2,000; for instruments, 1 in 2,000 and 3,000.

Compound Fracture of Patella.

Before an English medical society, recently, Dr. Altham read a paper on a case of compound comminuted fracture of the patella, and showed casts of the leg. The injury was caused by falling from a height of 17 feet on the bare knee. Comminution was so extensive that there was no hope of the bony fragments uniting; they were, therefore, removed, and the wound was dressed antiseptically, free drainage being provided. In six weeks the patient was able to walk about with the limb in splints, and little more than six months from the time of the accident the knee-joint had almost regained its normal mobility, though there was no patella.

The Microbe of Typhoid Fever.

At a recent meeting of the Société des Hôpitaux, M. Chantemeese made an interesting communication concerning the morphological and biological characteristics of the typhoid-microbe. The sporulation of this microbe takes place between 19° and 48° C. (67° to 104.4° F.). It develops in water, even if sterilized. At a temperature of 45° C. (113° F.) the cultivations live for several days; they are destroyed by boiling. This microbe retains its vitality in damp ground. Corrosive sublimate (1 in 20,000) and sulphate of quinine (1 in 800) destroy it. Carbolic acid (1 in 400) has no effect on it; hydrochloric acid is also inert, therefore the acidity of the stomach is not inimical to this microbe.

Inequality of Pupils in Healthy Persons.

From an examination of 134 healthy recruits, Dr. G. S. Ivanoff, of Kïrïlov, came (*Vratch*, No. vii., 1887, p. 162,) to the following conclusions:

1. Equal or symmetrical pupils, as well as equal or symmetrical halves of the face, are met with but very seldom, the former only in 9 per cent. of the persons examined, and the latter only in 2.2 per cent.

2. The inequality or asymmetry is probably dependent upon an asymmetrical development of the cerebral hemisphere.

3. In 54.5 per cent. of persons, the left pupil, and in 73.9 per cent. the left side of the face, is larger than the right one.

Iodol in Diphtheria.

In order to test the statements of Dr. Mazzoni, Dr. L. L. Stembo, of Vilna, tried (*Proceedings of the Vilna Medical Society*, No. v., 1887, p. 114,) the local use of iodol in seven cases of diphtheria, two of which were severe. The drug was applied either alone, in powder, or in the form of a solution (℞. Iodoil, ℈ss; liq. vini, ʒss; glycerini, ʒiijss). All the patients recovered after treatment lasting from four to six days. The advantages claimed by Dr. Stembo for iodol are its complete harmlessness, its freedom from unpleasant smell or taste, the painlessness of its application, and the absence of any untoward secondary effects, such as loss of appetite, nausea, vomiting, etc.

Local Temperature in Small-pox.

The *France Médicale*, of January 2, gives an account of some observations made by Dr. Montefusco, of Naples, on local thermometry in small-pox. He points out that, in that disease, the region of the spleen has always a higher temperature than the hepatic region and the abdominal walls. There is no constant relation between the local temperature of the spleen and the axillary temperature.

Correspondence.

Obstetrical Statistics.

Eds. Med. and Surg. Reporter:

A recent writer in your journal propounds this query: "What do you think of a country doctor having 960 cases of midwifery in sixteen years of general practice, and not losing a single case, or using the forceps in a single case?"

The doctor's experience has been an exceptionally bright one. It is very doubtful if any other reader of the Medical and Surgical Reporter can claim even half that number of cases without losing one or more mothers, and probably a child or two. A prolapsed cord is a grave menace to the child even in the most expert hands, and puerperal eclampsia is unfortunately not nearly so rare as the doctor's experience would lead one to suppose.

He has never owned or used forceps, denies their value (as well might he deny the the utility of craniotomy), and considers that one element of his success.

In a practice extending over eight years, the forceps were applied on an average about eight times yearly. Have attended four cases puerperal eclampsia in that time; one of these cases was delivered of a living child with the forceps, the convulsions ceasing upon delivery, and both did well. One of the others died, but the labor was otherwise normal, neither forceps nor ergot being used. In another case, the woman died with puerperal fever on the fifth day. But in all the cases in which the forceps were used, both mother and child made excellent recoveries. This is no more an argument for their general use than Dr. Davis' is for their disuse.

A properly constructed forceps can never harm a patient; an improperly constructed doctor can do very much harm, not only with the forceps, but with the hands as well.

The forceps occupy no space that is needed by the head of the fœtus. Properly applied, no patient should realize their presence, and does not, save from the relief their assistance gives. Let nature take her course, if you will, but when, as Dr. D. says, "she takes a wrong course," and it is necessary to assist her, he would find in many instances that a pair of forceps, backed by sound judgment, would be less injurious and far more effective than nine-tenths of his hand manipulation.

Geo. H. Rhoads, M. D.

Tobyhanna, Pa.

International Medical Congress, Washington, 1887.

Eds. Med. and Surg. Reporter:

I observe in your journal for March, 26 1887, a statement that "The item appropriating $50,000 for the Congress was placed in the Sundry Civil Appropriation Bill, and was therefore, we presume, passed." The fact is that although as you state $50,000 was placed in the bill by the Senate, the amount was cut down in the Conference Committee to $10,000, which will be barely sufficient to meet the absolutely necessary expenses of the Congress, but will not provide for entertainments of special character.

Very truly yours,

John B. Hamilton, M. D.

Secretary-General.

News and Miscellany.

The American Surgical Association.

The American Surgical Association will hold its annual meeting at Washington, on May 11th, 12th, 13th, and 14th. The preliminary programme, just issued, announces the following papers:

Dr. F. S. Dennis, on "The Exploration of the Bladder by the Suprapubic Method."

Dr. John H. Packard, on "Suprapubic Cystotomy for other purposes than the Removal of Calculi."

Dr. A. Vanderveer, "To What Extent can we Classify Our Cases of Vesical Calculi for Operation, with Report of Cases?"

Dr. J. Collins Warren, on "Resection of the Intestines; with Specimens."

Dr. C. B. Nancrede, on "Should Laparotomy be Done for Penetrating Wounds of the Abdomen Involving Viscera?"

Dr. T. A. McGraw, on "Laparotomy for Injuries of the Abdominal Viscera."

Dr. C. H. Mastin, on "Hernia; its Treatment," etc.

Dr. J. E. Michael, on "" Report of a Case of Ventral Hernia Successfully Treated by Operation; with a suggestion as to the method of operating."

Dr. Samuel W. Gross, on "The Prognosis of Sarcomata of the Breast."

Dr. D. Hayes Agnew, on "The Medico-Legal Aspect of Cranial and Thoracic Wounds (suicidal)."

Dr. L. McLane Tiffany, on "Surgical Diseases of the White and Colored Races Compared; Preliminary Observations."

Dr. B. A. Watson, on "An Experimental Study of Effects of Puncture of the Heart in Cases of Chloroform Narcosis."

Dr. J. Ford Thompson, on "Case of Vaginal Hysterectomy."

Dr. W. F. Westmoreland, on "Fibrocystic Tumor of the Jaw."

Dr. T. J. Dunott, on "Some Remarks on Hypertrophy of the Tongue, and the History of a Case."

Dr. J. A. Conninger, on "A Case of Varix of the Jugular Vein."

Dr. William A. Byrd, on "Excision of the Ankle-Joint."

Dr. David Prince, on "Wounds; their Aseptic and Antiseptic Management."

Dr. J. Ewing Mears, on "The Study of the Methods of Operation Practiced, and of the Results Obtained in the Treatment of Cleft of the Hard and Soft Palate, Illustrated by a Record of Fifty Cases."

Government Health Reports.

By direction of the Secretary of the Treasury, Dr. John B. Hamilton, Surgeon-General of the Marine Hospital Service, has issued the following abstract of sanitary reports received during the week ending April 14:

England and Wales.—The deaths registered in twenty-eight great towns of England and Wales during the week ending March 26th corresponded to an annual death rate of 23.5 in a thousand of the aggregate population, which is estimated at 9,245,099. The lowest death rate was recorded in Derby, viz., 16.1, and the highest in Manchester, viz., 35.4 in a thousand. One death from small-pox was registered in Portsmouth, 1 in Manchester, 1 in Blackburn, and 2 in Cardiff.

London.—One thousand seven hundred and twenty deaths were registered during the week ending March 26th, including 1 from small-pox, 77 from measles, 14 from scarlet fever, 13 from diphtheria, 42 from whooping-cough, 9 from enteric fever, and 9 from diarrhœa and dysentery. There were 509 deaths from diseases of the respiratory organs. Different forms of violence caused 63 deaths. The deaths from all causes corresponded to an annual rate of 21.3 in a thousand. In greater London, 2,156 deaths were registered, corresponding to an annual death rate of 20.8 in a thousand of the population. In the outer ring, 29 deaths from measles and 10 from diphtheria were registered.

Ireland.—The average annual death rate represented by the deaths registered during the week ending March 26th, in the sixteen principal town districts of Ireland, was 28.4 in a thousand of the population. The lowest rate was recorded in Wexford, viz., 17.1, and the highest in Drogheda, viz., 42.3.

Dublin.—Two hundred and twelve deaths were registered during the week ending March 26th, including 4 from measles, 7 from scarlet fever, 3 from whooping-cough, 1 from cerebro-spinal fever, and 3 from enteric fever. Diseases of the respiratory organs caused 53 deaths. In thirty-five instances the causes of death were uncertified. The deaths from all causes corresponded to an annual rate of 31.3 in a thousand.

Scotland.—The death rate in eight principal towns during the week ending March 26th was 25.9 in a thousand of the aggregate population, which is estimated at 1,299,000. The lowest mortality was recorded in Leith, viz., 10.8, and the highest in Aberdeen, viz., 36.8 in a thousand. The aggregate number of deaths registered from all causes was 646, including 55 from measles, 18 from scarlet fever, 6 from diphtheria, 31 from whooping-cough, and 14 from diarrhœa.

Germany.—The deaths registered in fifty-two cities of Germany, having an aggregate population of 6,763,937, during the week ending March 12th, corresponded to an annual death rate of 25.5 in a thousand. The lowest rate was recorded in Carlsruhe, viz., 14.4, and the highest in Augsburg, viz., 39.4 in a thousand. During the week ending March 19th, the deaths registered corresponded to an annual rate of 25.2. The lowest rate was recorded in Görlitz, viz., 14.5, and the highest in Augsburg, viz., 41.7 in a thousand.

Catania.—Twenty-one cases of cholera and 11 deaths from that disease were registered during the week ending March 19th. The consul states that "nearly all who can get away from the city have gone to the slopes of Etna and elsewhere. The city is almost deserted. Business is paralyzed, the poor are suffering, not being able to get work. There is no doubt but that there have been more cases and deaths than reported. The people have a terror of the lazaretto; hence, when a friend or relative is attacked, often they do not report the case, and the sufferer does not have the advantage of good treatment. Good water is now conducted into the city in closed conduits. The wells have been closed. It is hoped that this may improve the public health.

Havana.—Five hundred and forty deaths were registered during the month of March, including 8 from yellow fever, 6 from enteric fever, 1 from bilious fever, 3 from pernicious fever, 2 from small-pox, and 6 from diphtheria. Yellow fever caused 4 deaths during the week ending April 7th.

Maracaibo.—The United States consul, in his dispatch dated March 7th, in relation to the subject of inoculation as a preventive of yellow fever, briefly mentioned in Abstract No. 51, inclosed copies of letters from the Venezuelan consul at Cucuta, Colombia, and from Dr. Bustamente, of the same city, from which it is learned that "Dr. Urricoechea, surgeon of the frontier battalion, inoculated, by way of experiment, and with good results, five of his soldiers. Twenty minutes after the operation the temperature gradually ascended to 40° C., accompanied with all the symptoms of yellow fever. This lasted forty hours, at the expiration of which had disappeared the fever and all attendant symptoms. This operation was effected in a place called Moras, three leagues from Cucuta, and where a body of troops is stationed, who have not come to this city for fear of the fever. At present the inoculated soldiers are here, exposed to the action of the focus of infection. As in Moras, no case of the epidemic has as yet presented itself." Dr. Bustamente, in his letter, states that "as my labors in the field of inoculation as a preventive of yellow fever are only, it may be said, mere experiments, which, although they may satisfy me with a well-founded hope of successful and complete result, cannot be of genuine utility until the best and most efficacious method is decided upon; I am thinking, however, of making an abstract of my observations, together with the method pursued, the results obtained, and everything that may be useful, in the premises. For the present I will confine myself to the statement that in more than forty persons whom I have inoculated, a fever, with many of the characteristic symptoms of yellow fever, has presented itself; this fever, developed by inoculation, varying several tenths of a degree, and in some cases ascending to 41° C., but never presenting the most grave symptoms of yellow fever. The result of my observations permits me to state positively that the fever produced by inoculation is attended with no danger, and it is safe to inoculate, as I have already done, from children of two years of age to the oldest invalids. Many of the persons inoculated have come to this city, and in no case has the yellow fever attacked them, which gives me hope of a final result completely satisfactory. The municipality, assisted by the merchants, sent to Mexico, January 10th, a commisson composed of two physicians, in order to study the inoculation of the fever."

Paris.—One thousand three hundred and fifty-six deaths were registered during the week ending March 26th, including 62 from measles, 5 from small-pox, 13 from whooping-cough, 44 from enteric fever, 3 from scarlet fever, and 31 from diphtheria.

Warsaw.—Two hundred and thirty-one deaths were registered during the week ending March 19th, including 5 from small-pox.

Trieste.—Ninety-eight deaths were registered during during the week ending March 12th, including 1 from enteric fever, 1 from scarlet fever, and 2 from diphtheria. Two cases of small-pox were registered, but no deaths from that disease.

Havre.—Sixty-four deaths were registered during the week ending March 26th, including 1 from small-pox, 1 from enteric fever, 3 from diphtheria, and 1 from homicide.

Palermo.—One hundred and ten deaths were registered during the week ending March 26th, including 1 from enteric fever, 4 from scarlet fever, and 8 from diphtheria.

Genoa.—One hundred and twenty-seven deaths were registered during the week ending March 26th, including 3 from small-pox, and 2 from enteric fever.

Amsterdam.—Two hundred and twenty-eight deaths were registered during the week ending March 26th, including 1 from enteric fever, and 3 from diphtheria.

Copenhagen.—One hundred and fifteen deaths were registered during the week ending March 22d, including 8 from diphtheria.

Toronto.—Thirty deaths were registered during the week ending April 2d, including 2 from enteric fever, and 2 from diphtheria.

Three Rivers.—Seven deaths were reported during the week ending April 9th, including 1 from diphtheria.

The Connection Between Chemical Constitution and Physiological Action.

At a meeting of the Royal Society on Thursday, March 31st, Drs. Lauder Brunton, and Cash made an important contribution to our knowledge of the Connection between Chemical Constitution and Physiological Action. In a former paper, the authors had discussed a number of the compounds of ammonia, and in the present they took up a number of substances allied to carbolic acid. A certain parallelism was observed between the changes of physiological action noticed in the compounds of ammonia and in those of benzene by the introduction of chlorine, bromine, iodine, and hydroxyl. Although these radicals do not modify the action of benzene so much as that of ammonia, yet, both in the ammonia compounds and the benzene compounds, the iodine seems to produce a greater tendency to paralysis of motor nerves, while hydroxyl tends to cause irritation of the nervous centres and tetanic convulsions; so that both solutions of ammenia and carbolic acid act on the frog as convulsant poisons in somewhat the same manner as strychnine. One marked peculiarity of the benzene compounds, however, is their tendency to cause tremor of various kinds, so that some of them produce in the frog symptoms like those of disseminated sclerosis in man, and others a form of locomotor ataxy.

The South Carolina Medical Association.

The South Carolina Medical Association held its thirty-seventh annual meeting at Aiken on the 12th and 13th of April, under the presidency of Dr. Cornelius Collock, of Cheraw. A number of interesting papers were read, and the Society recommended the establishment of a State Medical Examining Board, the members of which should be appointed by the Governor, from nominees presented by the South Carolina Medical Association.

The following officers were elected for the ensuing year:

President—T. Grange Simons, M. D., of Charleston.

Vice-Presidents—James Evans, M. D., of Florence; Thomas Legare, M. D., of Charleston; and D. S. Pope, M. D., of Columbia.

Secretary—W. P. Porcher, M. D., of Charleston.

Treasurer—H. W. De Saussure, Jr., M. D., of Charleston.

The next meeting will be held at Columbia, on the second Wednesday in April, 1888.

M. Pasteur's Intensive Inoculations.

Those who are exercised lest M. Pasteur's latest form of inoculation may communicate rabies to healthy persons are not always temperate in their expressions, if we may judge by a letter which Professor Pajot recently addressed to the editor of the *Journal de Médecine de Paris*. Although M. Pajot professes his readiness to contribute to a fund for raising a statue of Pasteur, in case it is proved that his practice is successful, he urges its trial on criminals condemned to death, the inoculations to be done under the supervision of a commission consisting of *two fanatics* (presumably, believers in the Pasteur system), two opponents of the method, and a presiding officer chosen by the four.

The Pennsylvania State Board of Health.

The sixth regular meeting of the Pennsylvania State Board of Health was held in Harrisburg on Thursday, April 14. While much routine business of importance to the State was transacted, the chief interest of the occasion to the public centred in the Annual Address before the Board, which was delivered in the hall of the House of Representatives on the evening of the same day by the Hon. E. A. Wood, M. D., of Pittsburgh, formerly a member of the State Legislature, who will be remembered by his colleagues in that body as a brilliant, forcible, and witty speaker. His address was worthy of the occasion, and an intellectual treat to all who had the good fortune to be present.

A Cure for Diabetes.

In a paper recently read by M. Martineau before the Société de Therapeutique of Paris, he claims to have treated diabetes with invariably good results for ten years past by means of a solution of carbonate of lithium and arsenate of sodium in ærated water, which is taken not only with meals, but whenever the patient is thirsty. He claims by these means to have cured sixty-seven diabetic patients who have been under his care.

Portrait of Dr. Koch.

Messrs. Parke, Davis & Co., Detroit, Mich., have published a large and excellent portrait of Dr. Robert Koch, the eminent bacteriologist. With characteristic liberality, they authorize us to say that if any physician will apply to them for a copy, mentioning this notice, they will send him one without charge.

Therapeutic Notes.

Emulsion of Cod-Liver Oil.—The emulsion of cod-liver oil prepared by Messrs. Scott & Bowne, New York city, is distinguished for its purity, permanence, and smoothness. In cases where it has been tried, it has agreed well with the stomach, and we believe is not surpassed by any other in the market.

Personal.

—Dr. W. B. Atkinson, 1400 Pine street, Philadelphia, is prepared to execute literary commissions for physicians, such as revising MSS., supplying articles, arranging indices, collating authorities on special subjects, etc. Dr. Atkinson's extensive experience in medical literature eminently qualifies him for these studies.

Items.

—Consumption is quite prevalent in Dakota, according to Dr. J. E. Engstadt, in the *Medical Age*. The Indians especially suffer from it, and so do the Norwegian immigrants.

—An International Congress of Cremation is to be held at Milan in September, 1887. Among the honorary presidents are Sir Henry Thompson, of London, and Professor Moleschott, of Rome.

—The sum of $700,000,000 is spent annually for alcohol by the 15,000,000 drinkers of this country, and the sum of $600,000,000 by the 8,000,000 drinkers of Great Britain and Ireland.

—A prize of $2,000 (10,000 francs) is offered by the Académie de Médecine, Paris, for the best work on the treatment of stricture of the urethra, or on the therapeutic methods for diseases of the urethra.

—A new medical journal is to be published shortly in Paris, under Professor Grancher's direction. It will be called the *Univers Médical*, and the editor intends to devote a much larger part to foreign news than is usually given in French papers.

—The Norwegian Government has taken another step towards discovering the origin and nature of leprosy, which is so common on the west coast of Norway, by despatching Dr. G. A. Hansen, director of the Leprosy Hospital at Bergen, to this country, for the purpose of inquiring into the heredity of the disease among Scandinavian emigrants to the United States.

—In the preface to the last edition of an English medical work entitled "What to Do in Cases of Poisoning," the author, Dr. Murrell, says: "This work has reached a fifth edition, but it is not my fault, and I disclaim all responsibility in the matter. I am told that it has been the means of saving many lives, and I have no doubt this is true, for I hear that a gentleman who thought of poisoning himself changed his mind on reading the directions for treatment."

OBITUARY NOTICE.

James Stewart Jewell, M. D.

From the *N. Y. Med. Jour.* we learn that James Stewart Jewell, M. D., of Chicago, died on Monday, the 18th inst., in the fiftieth year of his age. For several years he had been the subject of a disease which, it was plain to his friends, forbade the expectation of his reaching a much greater age. He was emaciated, sallow, and feeble in body, but the brilliancy of his mental powers and the charm of his conversation were in nowise dimmed on the occasion of his last visit to New York, some months since, whatever may have been the case towards the close of his life.

Dr. Jewell, who was of mingled Scotch and English ancestry, was born September 8, 1837, near Galena, Illinois. He took his medical degree from the Chicago Medical College in the year 1860, and began practice in Williamson county. In 1862 he changed his residence to Chicago, and has since been widely known as one of the most eminent physicians of that city, and indeed of the whole country—first as a general practitioner and afterward as a neurologist and as a writer. During the late civil war he served as a contract surgeon in General Sherman's army. For many years he occupied the chair of nervous and mental diseases in the faculty of the Chicago Medical College, and was the professor emeritus at the time of his death. He was one of the founders of the *Journal of Nervous and Mental Disease*, and for several years its chief editor. Most of his literary work was published in that journal. More recently, when he had recovered to some extent from the debility consequent on his malady, he began the issue of a new journal, the *Neurological Review*, but, unfortunately, was soon compelled, by the renewed inroads of his fatal disease, to suspend its publication.

Dr. Jewell was held in the highest esteem by his fellow-workers in neurology, and was respected, admired, and most warmly regarded by all whose good fortune it was to be brought into contact with him.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1054-1556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

THE HYPODERMATIC USE OF BIMURIATE OF QUININE AND UREA IN THE PRACTICE OF MEDICINE.

BY R. P. TALLEY, M. D.,
Of Belton, Texas.

Doctors of medicine, like trees, begin to die when they cease to grow.

Before entering upon my subject I must crave the indulgence of those who heard me at Tyler in 1883, and at Belton in 1884—And for reasons to wit:

1st. I hope here to answer some criticisms made in the discussion of my paper on this subject at our meeting at Belton, and some others contained in *The Texas Courier Record of Medicine*, vol. 11, No. 1, page 61. 2d. The errors by myself and the publishing committee contained in this paper as published in the transactions of the Texas State Medical Association for 1884, are so many and of such character as to render it almost worthless to convey the ideas I intended, that I am constrained to try once more to do better. (*The publishing committee started out by heading my paper* Bichromate *instead of* Bimuriate of Quinine and Urea.) More! notwithstanding the noise I've tried to make on this subject, I have heard but little, either directly or indirectly, from the profession; and having had some experience since our meeting at Belton—some of which is almost too sore to tell—I hope that by raising the question again to further advance the doctrine of Hypodermatic Medication with Quinine—therefore, will those who can have no interest in this matter, pardon me for my (I hope not too great) enthusiasm on this subject. I want it distinctly understood that I am not writing to urge the importance of the use of quinine in the practice of medicine. I believe that all the world now considers its use to be the most important treatment yet discovered for all purely malarial diseases, as well as of much value in many other "ills to which flesh is heir." But I do want to insist on the importance of the use of this particular preparation of quinine, and upon its administration in proper doses—doses not too large—by the hypodermatic method, in preference to *all* others in *all* cases of any severity.

I will now give, as briefly as I well can, some of my personal experience and observations in the management of malarial diseases with quinine and its salts in Central Texas during the last eighteen years.

In 1867, August 3d, I made my first professional visit in Texas, near Davilla, Milam county. It will long be remembered, that from about 1866 to 1870, almost our entire population suffered severely from malarial disease, and especially from what was known among the laity as "black jaundice," which many physicians now call "malarial hæmaturia." The practice where I was then located, was *fearfully* routine: quinine, calomel, and purgatives, in almost every case, made up the work of the doctor. A physician knew about as well what would be his treatment before he saw his patient as he did afterward. The laity believed so much in purgatives, pills, and especially some form of mercury, that if they could not get them any other way, they would take some even in spite of the doctor.

I noticed in such practice a difficulty in getting any effects from quinine, even the symptoms of its physiological action, especially for several days in the beginning of the treatment of cases of any severity. I was told by some professional friends of more experience than myself, and I also read from the little current medical literature at my command at that time, that the system must be first prepared for the quinine by the use of mercury, purgatives, etc.; and again from the same source of information it was urged that if quinine was not absorbed by the stomach, the secretion of which is normally acid, it would likely become entangled in mucus, etc., and pass into the small bowels, and that here, the secretions being normally alkaline, the salts of quinine would be very insoluble, would not be likely to affect the patient at all. I next tried and succeeded much better with sulphate of quinine by the mouth, in solution in plenty of water and sulphuric acid quantum sufficit. But this preparation was so very disagreeable to take, and it was so difficult to keep the stomach from rejecting it, that my patients called loudly for some way of taking their quinine not so disagreeable. All of this I found, after much sore trial, did not give any satisfactory information or results; I found that in many cases my patients would not complain of the characteristic effects of quinine until after three or four days' treatment, or in other words, *after convalescence had actually set in notwithstanding the daily rations of the drug.* In this experience it occurred to me that perhaps it was well for the patient that quinine by the stomach in the beginning of malarial fevers should not be absorbed, because, being mixed up more or less with vitiated matters, almost always in the alimentary canal in such cases, if absorbed it would likely carry with it other foreign matters not good in the circulation, and that nature would in many cases succeed in resisting the disease as well as the doctor.

On one occasion, several years ago, I was called to see an orphan negro boy, who was very sick with remittent fever, and who had no friends to give, or even urge me to give, the traditional mercury and purgatives. I gave him 10 grs. sulphate of quinine made in pills, with aromatic sulphuric acid, every morning, with all the fluids and nourishment he could be induced to take. This treatment was continued for three days, during which time he drank and retained some water and a good deal of buttermilk. He improved every day, and on the evening of the third day I gave him a full dose of castor oil, yet his bowels did not move for about twelve hours, the actions from which were saved for "the doctor to look at." I of course examined them carefully, and to my surprise found eight of the twelve pills above referred to.

This was my first tangible, physical evidence that the salts of quinine might remain in the alimentary canal so long and not be absorbed. But I have frequently since seen cases essentially similar. Not long ago I gave a little girl, about ten years old, sulphate of quinine in capsules—the quinine made into mass with citric acid and water, from Wednesday until the following Saturday. She improved every day, and on Saturday morning I examined a spontaneous action from her bowels, the first while taking the capsules, and found several doses, the capsules gone, but the mass not perceptibly less than when put into the capsules.

We read from some eminent scientific experimenters, that in health ordinary doses of quinine by the stomach may all, save about four per cent., be recovered from the urine in from six to twelve hours after taking it. But they also say that in disease it frequently does not make its appearance in the urine for several days; therefore I conclude that when our patients most need quinine they may get the least of it when we attempt to administer by the stomach.

Cases similar to that of the little girl above mentioned, have been observed by many of my professional friends with whom I have communicated on this subject since our meeting at Belton.

This experience, and that of frequently finding patients who would only speak of the characteristic effects of quinine after taking it from three to five days, either in powder, pill, or capsule, the patient most frequently improving in the meantime, but sometimes dying—*perhaps*, simply for the want of the constitutional effects of quinine—has given me a great deal of trouble in the practice of medicine here where we have so many malarial diseases with which to contend, especially since all the medical world so earnestly insists that quinine is the very best drug with which to treat all purely malarial diseases, as well as all troubles even near akin to malarious affections.

At times I have become so skeptical in regard to its use by the stomach that I have been seriously tempted to use some substitute perfectly inert, something that would at least do no harm, as quinine no doubt frequently does. I am satisfied beyond any reasonable doubt that if the United States had on hand

to-day the quinine that has been uselessly and harmfully used during the last twenty years, it would "go begging" at a nickel an ounce. There would be no quarreling in our Congress about import duties on it. M. Michel Levy informs us that "at the Lille Military Hospital, the physician in charge *cured intermittent fever* (italics mine) with pure water, which he dispensed in vials labelled "Protoxide of Hydrogen." Please take due notice that the physician in charge of Lille Military Hospital says he *cured intermittent fever* with pure water dispensed in vials, etc. Would it not have been better and nearer the truth for him to have conveyed the idea—the abstract fact—that his patients got well of intermittent fever *while* they used pure water dispensed in vials labelled "Protoxide of Hydrogen?" His cure with pure water in this way is a parallel of my patients above mentioned, who got well of malarial fever *while* I give quinine, the quinine having no effect at all. Cure thus carelessly asserted has done more to retard progress in what is known as curative medicine than any other word in use. Too many physicians are too often so anxious to see themselves efficient agents rather than interested spectators that they wholly neglect or otherwise fail to see their blunders. To us as physicians, it is sickening and discouraging in the extreme to see so many of our observations so vitiated by tangible errors as to render them worthless, as having surely done great harm. We can only be saved by the doctrine that "the moral quality of an act resides in the intention," when possibly we ought to look for distinct and definite results in medicine. Reports of failure when intelligently made are worth more than those of success, which are too often only *apparently* so. I believe it is a good idea for a physician "never to believe anything in medicine as long as he can help it." "The study and practice of medicine are wonderfully calculated to steal away a man's common sense." (My Note Book, Bowling.)

But notwithstanding all this, I am compelled to have much faith in quinine in the treatment of all malarial diseases, especially since my experience with it for nearly four years by the subcutaneous method of administration. I have been studying and watching medical literature the very best I could for several years for some preparation of quinine that could be used efficiently with the hypodermatic syringe. Formula upon formula has been published for the last thirty or forty years for preparing the various salts of quinine for hypodermic use, but all of them with but one exception, so far as I now know, are so defective for reasons not here necessary to give, that I have used them only as a last resort, notwithstanding that medical literature as well as my experience in regard to their use are very encouraging in many respects.

About four years ago I read in Prof. Bartholow's third edition of "Hypodermatic Medication," as follows, to wit: "*Very recently* (italics mine) a new compound salt of quinine has been introduced for hypodermic injection, and it *seems* (italics mine) to possess very distinct advantages over all other preparations hitherto proposed. It has been termed quinia bimuriatica carbomidata, and is formed by Drygen from a combination of twenty parts of muriate of quinia, twelve parts of muriatic acid, and three parts of urea. The resulting salt is soluble in *equal parts* of water (italics mine)." He further says, "The trials that have been made of it at Hamburg have proved so successful that it is highly desirable it should be known more widely. A 50 per cent. solution has always been employed, and the quantity injected has varied from a half to three syringefuls. The local irritation was in most cases very slight, and at the worst consisted in a circumscribed burning pain, without redness or swelling." When I first read this I felt as if I had captured a prize, the value of which in the practice of medicine could not easily be overestimated, unless quinine has been by all the medical world up to this date fearfully overestimated.

Over three years ago I wrote Prof. Bartholow for reference to any literature on its use hypodermatically, besides what was contained in his 3d ed. on "Hypodermatic Medication." He soon answered as follows:

"1509 WALNUT STREET,
"PHILADELPHIA, *March* 17.

"*Dear Doctor:* In reply to your note, I have to say that all the information possessed by me on the subject of the subcutaneous use of quinine and urea is contained in the 4th edition of my Manual of Hypodermatic Medication.

"There have been incidental references to the subcutaneous injection of quinine, and to this preparation, but there have not been brought forward any actually new facts.

"Very truly,
"ROBERTS BARTHOLOW."

I then very soon obtained his 4th ed., and found that it contained substantially the same and nothing more than the 3d ed. on this particular subject. About one year later I wrote Messrs. John Wyeth & Bro., of

Philadelphia, to please give me the difference in the chemical composition of sulphate of quinine and bimuriate of quinine and urea, especially in regard to the amount of quinine contained in each. These gentlemen replied as follows:

"PHILADELPHIA, PA., *March* 8, 1884.

"DR. R. P. TALLEY, BELTON, TEXAS.

"*Dear Sir:* Your esteemed favor came duly to hand, and in reply permit us to say, that the salt in question (bimuriate of quinine and urea) has been extensively used of late in Philadelphia and its vicinity. There have been so many formulas given that for the present we prefer to withhold any comments on them. We herewith hand you an extract taken from the *Druggist's Circular* in relation to the preparation.

"We take pleasure in handing you the formula showing the different amounts of quinine contained in each preparation—of sulphate of quinine and of bimuriate of quinine and urea, viz:

"Sulphate of quinine=alkaloid, 73.134; Bimuriate of quinine and urea=alkaloid, 61.36; or about this percentage. * * * * *

(Signed.) "Yours truly,

"JOHN WYETH & BRO."

So we see that the new preparation contains a little less of the alkaloid (quinine) than the sulphate of quinine, and this in using the new preparation is important to know, inasmuch as our doses must or ought to have reference to the active principle contained in them, rather than to anything else simply to prepare them for use.

While the above detail is too tedious for a meeting like this, it goes to show *some* of the troubles we have to encounter in the practice of medicine.

I will now give a few cases to illustrate my experience in the use of this new preparation of quinine.

Case 1. I treated my first case October 1, 1882. It was a boy about ten years old, who had been sick two days with intermittent malarial fever. When I first saw him I found his temperature 105½°, pulse 120, respiration 30 to 35, vomiting every few minutes, cold extremities, and almost complete coma, with twitching of the muscles of the right side of the whole body. Bowels had been moved several times with "Simmons' Liver Regulator," and he had had several domestic doses of blue mass and sulphate of quinine during the last two days. I gave at about 10 a. m., hypodermatically, sulph. of morphine, gr. ⅛, sulph. atropine gr. $\frac{1}{200}$, bimuriate of quinine, and urea gr. x. in water, ♏x. Ordered a warm sponge bath to the whole surface of the body, and for him to have all the iced lemonade he could be induced to take. At 6 p. m. temperature 102°, and a corresponding improvement in every other respect. Did not vomit after taking the hypodermatic injection—an important effect of the morphine and atropine perhaps—and had drank freely of the lemonade. He convalesced favorably and rapidly without any other drugging, and did not relapse, as is so often the case in such diseases.

Now, in this case I want to call attention to this, to wit: That the convalescence was of but little value as reliable evidence as to the direct efficiency of the treatment, only in that the patient did not relapse, because, in my judgment, such cases have a natural tendency to convalesce after the third paroxysm, but also a natural tendency to relapse in from seven to fourteen days etc., according to their type, and this boy already having been sick three days with the every-day type of malarial fever, perhaps was just ready to get better any way.

Case 2. November 5th, 1882, about 2 o'clock p. m., I saw Mrs. I. at the request of her husband, from whom I got substantially the following history, which I regarded as about correct, inasmuch as he had about ten years' experience in a retail drug store: Patient had a chill on the 2d and 3d inst., followed by fever and sweating as in ordinary intermittent malarial fever. On the 4th inst., she seemed a little delirious, but took some nourishment in the morning as on each of the two previous days; but early in the afternoon she fell from her seat in a spasm, and had been in a profound coma ever since, with frequent convulsive movements. The family physician was sent for and arrived soon after the spasm came on. He gave a hypodermatic injection of morphine, ordered mustard plasters to her spine, and then tried to control the convulsive movements with chloroform by inhalation.

About 8 or 9 o'clock p. m., he left her no better, instructing her husband to give her chloroform freely, and not to be afraid of it, and to let him know if she got better, and gave as his opinion that she was suffering from malarial toxæmia. But little chloroform was used. The family physician was sent for and arrived again about daylight the following morning. He in vain tried again to control the trouble with inhalations of chloroform. and about 8 or 9 o'clock a. m., left her to her fate, saying to her husband and friends that nothing more could be done

for her, and that he thought she was then dying and would likely be dead within an hour. On my arrival, I found her condition about as follows:

Pulse 120, full and bounding; respiration 25 to 30, very labored and noisy; temperature 106°; eyes wide open, the pupils turned up and dilated to their fullest extent, and the conjunctivæ intensely congested. Her hips were almost enveloped in involuntary actions from her bowels and bladder. The upper extremities more or less flexed, the lower straight, and both in a constant spasmodic condition; the head drawn back and to the left. The coma at this time was profound. She had not had anything, not even water, by the mouth for about twenty-four hours, and could not then take anything, paying no attention at all to anything put into her mouth. I diagnosed the trouble pernicious malarial fever, with very unfavorable prognosis, and treated the case as follows:

I first had her clothes all taken off and her whole body well washed in tepid water, then placed in a clean bed between two open doors, with no covering except a sheet. I then gave subcutaneously sulph. of morphine, gr. $\frac{1}{3}$; sulph. of atropine, gr. $\frac{1}{60}$; bimuriate of quinine and urea, gr.xv, in solution in water, ♏xx. Also ordered a pint of warm water to be slowly injected into the rectum, and to be kept in by force for one hour, about every four to six hours. The whole body to be sponged every hour with warm water, until my return about six o'clock p. m. Within ten minutes after the subcutaneous injection the respiration and pulse were very much improved, and she never had any more of the spasmodic movements above referred to. At 6 p. m., temperature 102°, and some improvement in all the other symptoms. I added some covering and ordered the treatment otherwise continued, except to give her water by the mouth instead of the rectum, if at any time she could so take it, and also discontinued the warm sponging, unless the skin seemed to get hot and dry again.

Nov. 6th, 8 a. m., about as at last visit, except with the water enemas a great deal of fecal matter with some urine had been involuntarily discharged, and she had uttered in a sort of delirious way several indistinct words, the first attempt to speak a word in any way for over thirty-six hours. I repeated the hypodermatic injection and ordered the other treatment continued. At 6 p. m., I found her very much improved in every respect. She had voluntarily taken plenty of water, but yet had considerable delirium. I ordered milk gruel or buttermilk as nourishment, and all the lemonade she could be induced to take as drinks.

November 7th, 8 a. m. About as at last visit, except some improvement in the delirium, but would occasionally utter the most hideous delirious screams I ever heard from any one, under any circumstances, and had taken some nourishment and freely of lemonade. I repeated the hypodermatic injection, and ordered the other management continued. At 6 p. m. decidedly better in every respect.

November 8th, 8 a. m. Dismissed the case with special instructions as to food, etc. Will note here that the temperature was never over 101° after the first day's treatment. Patient made a rapid recovery without any further drugging, and had not up to April, 1885, had another attack of malarial fever.

Case 3d. August 12th, 1884, I saw a child two years old, who had been very sick for three days with remittent malarial fever. At my visit (about 3 o'clock, p. m.) it was in a deep coma, and its temperature 106°. Its family had been living in the Leon river bottom for some months, and the child had several attacks of malarial fever during this time, and was then very anæmic. It had been treated—domestically—with a large quantity of sulphate of quinine and some calomel, during this immediate attack, and had taken, as its father said, "a bottle of quinine in the last two or three months." For treatment I gave bimuriate of quinine and urea, gr.iv.; sulph. of morphine, gr. $\frac{1}{12}$; sulph. of atropine, gr. $\frac{1}{240}$, in solution in warm water, q. s. Then ordered a warm sponge bath every thirty minutes until the child could swallow (if ever), and then to have all the buttermilk and lemonade it could take until it was decidedly better. Two days later I was informed that the child was still living, and that while it was better in every way, its parents wanted me to see it again. At this second visit I found the little fellow looking fearfully pale, very weak, somewhat deaf, a little fever, and poor appetite. After giving careful advice in regard to diet, etc., I gave—with doubt as to its propriety—another dose of the hypodermatic injection. About four months after this I learned from the child's father that it got well right away, and had been well ever since, except that it was still "very hard of hearing," but that his other children were "chilling right along," and had been for about six months.

Case 4th. The following case has been the sorest of my experience with this treatment, although it *may be* that some have died by the injudicious use of this or for the want of a better treatment.

In 1883, September 11th, Mr. D. called me to see his son, who was about ten years old, poorly developed, and had had malarial fever, to my own knowledge, from time to time for several months, during which time he had been living in the Leon river bottom. He had been sick with this attack about three days, in which time his father had consulted me at my office every day, and I had at each of said consultations prescribed the routine treatment, to wit: Sulphate of quinine, mercury, lemonade, etc., by the mouth. At my visit in the morning his temperature was 104°, and so much delirium that it was almost impossible to get him to take anything by the mouth. His delirium was very much like delirium tremens. In this case I shall only give in detail the hypodermatic part of the treatment, and, as I think, its results. Suffice it now to say that I gave half of the hypodermatic dose used in case 2d. At about 4 o'clock p. m., his temperature was 101½°, with other improvements, except we could not get him to understand what we wanted him to try to do. This condition I then took to be from delirium, but now think it was from deafness. The next morning I found him in the same condition, except he had taken some milk and plenty of lemonade and some water, and would gaze at persons about his bed with a sort of wild expression of countenance. Fearing another paroxysm, I "popped in" (an expression peculiar to quack doctors of medicine) another dose of the hypodermatic injection and with it, I *now* think that I popped his capacity to ever hear again out of existence. At least I *know* he could hear up to a short time before my first visit, and also that he has not been able since to hear a watch tick resting firmly against his ear. Also the history from his father is, that his son had had several "risings in his head and running from his ears," when younger, but there had not been anything wrong with his ears for some time before I treated him, and that there had not been anything wrong with his ears since so far as he could tell, except his deafness. The only consolation I have in this error in practice (if it is one) is that with the kind assistance of Dr. R. H. Chilton, of Dallas, Texas, and a good lawyer of my town, the patient has been in the deaf and dumb asylum at Austin, Texas, for nearly two years, and has so much improved in every respect, except in his capacity to hear, that when he again mixes with his family he hardly looks like one of the same tribe, notwithstanding his parents are just as clever as any poor people, living on a rented farm, well can be.

Now, I believe in my great anxiety for him I gave this poor boy too much quinine—in other words, I over-treated him, as we poor mortal doctors too frequently do. That is, where our patients most need our cool and calm judgment, judgment is out and anxiety with too much desire to be efficient agents is in, upon the physical principle, that "two bodies cannot occupy the same space at the same time."

Dr. Chilton saw this boy April, 1884, and after carefully examining his ears, gave it as his opinion that such organic changes had taken place that no sort of treatment could possibly cure or even benefit him materially. Since writing the above I have had a conversation with Dr. Chilton in regard to the effects of quinine in producing this boy's deafness and he (Dr. C.) insisted that he cannot believe the quinine had any bad effect in this case, and that I was in all probability wrong in charging myself with the boy's deafness. Having a high regard for Dr. Chilton's opinion as a specialist, I concluded to reinvestigate the subject before blaming myself too much in this case and in such practice. So I did, and will offer authority for my conclusions above and such as may follow, to wit:

In "A Practical Treatise on the Diseases of the Ear, by Prof. Roosa," ed. of 1883, pages 619 to 626, he says, "In a paper read by me before the Society of Neurology and Electrology in April, 1874 (which was published in the American Journal of the Medical Sciences, vol. lxviii, page 400), I classified four cases of congestion and *inflammation* (italics mine) of the base of the brain and labyrinth, caused by the internal administration of quinine. My remarks at that time led to a discussion in which Drs. Jacobi and Hammond participated. To attempt a settlement of some of the questions involved, I undertook some experiments upon the human subjects, as did Dr. Hammond upon animals. I believe these were the first experiments to determine the effects of quinine upon the ear. They have been followed by others, and considerable clinical experience has been duly published as to the effects of quinine upon the eye as well as the ear, so that the views of the profession is now clearer than before the subject was thus opened up." * * * "Fortunately most of the cases of

deafness caused by quinine fully recover. In some however, most deplorable results occur."

Kirchner states as the result of his experiments that "quinine causes (*i. e.*, may cause) inflammatory processes and permanent pathological changes in the ear."

Orne Green (*Boston Medical and Surgical Reporter*, vol. cviii., p. 220), after reviewing the literature of the subject and giving his own large clinical experience, quotes Prof. Roosa's views and their corroboration by Kirchner, with approbation, and states: "From our present knowledge, both clinical and experimental, we are justified in asserting that the action of quinine upon the ears is to produce (i. e., in large doses, if I understand him) congestion of the labyrinth and tympanum, and sometimes distinct inflammation with permanent tissue changes."

After studying medicine the very best I could for about twenty-five years, I am sorry to say that I am in more or less doubt as to whether quinine has up to this date been a blessing or a curse, even in the hands of those who claim to be REGULAR DOCTORS OF MEDICINE, to say nothing of the miserable haphazard manner of using it by quack doctors and the laity the world over. So much for Case 4 at the present.

To detail any more cases treated in the manner indicated would make this paper too long, especially since medical literature and experience furnish abundant evidence that the hypodermatic method of using quinine in the treatment of malarial diseases is beyond any reasonable doubt far superior to any other mode of using it yet discovered. With a single proportional dose of the above indicated hypodermatic preparation I have frequently relieved, *as I thought*, children suffering from the worst forms of malarial fever, and without any other drugging and without a single so-called relapse, so far as I now know.

Dr. Casseaud treated (so says Dr. Bartholow), in the hospitals at Smyrna, one hundred and fifty cases of malarial fever by the subcutaneous injection of quinine (he does not say what preparation), and had but one relapse. Prof. Bartholow, of Philadelphia, Pa., says, in speaking of Dr. Casseaud's success; "Such have been my own observations." Dr. Moore, of the Bombay Medical Service, concludes "that four or five grains of quinine injected beneath the integument are equal to *five* or *six times that amount* (italics mine) taken into the stomach."*

*According to this experience you see not only the force of this method of using quinine, but also my error in the Case 4 above reported.

With the hypodermatic preparation used in the treatment of the four cases above detailed, I have only *quinined* a few cases of pure typhoid fever, and in all, I think, with more or less doubt as to my good results, especially as a direct antipyretic. But Prof. Bartholow says: "The antipyretic effects of quinine are constantly made use of in the treatment of continued fevers, as all the world knows, the treatment being by the mouth." I cannot believe much in the direct antipyretic effects of quinine in typhoid fever. Perhaps it is of service in such cases in its effects in controlling pyæmic and septic conditions. At any rate, under no circumstances can I be induced to give quinine in such enormous doses as many physicians warmly advocate.

I know that some of my professional neighbors are in the habit of giving from ʒi. to ʒii. in twenty-four hours; some even give ℥ss in twenty-four hours. A professional friend of mine not long ago gave his own daughter ʒi bimuriate of quinine and urea with morphine and atropine, in four doses in twenty-four hours, and yet no apparent bad effects followed. But she has a serious eye trouble (just the nature of which I do not know) which he says followed a serious attack of fever for which he used a very large quantity of quinine. It is my opinion that in the use of large doses of quinine, by the mouth, one of three effects may be expected with more or less certainty, to wit: 1. It will have no effect at all, not being absorbed; 2. A certain per cent. *may* take effect; 3. It may all be absorbed, and if so, will always do some harm and sometimes serious mischief. Hence, I must insist that when administering it by the mouth we do not and can not know where it is or what effect it will have for good or for evil. Many worthy and reliable observers insist that too large doses of quinine will not only produce permanent injury, especially to the eye and ear, but also actually death, in many cases, especially when co-operating with some fearfully diseased condition of the system. I am satisfied beyond any reasonable doubt, that many deaths reported as caused by "brain fever" and "congestion," etc., etc., were in fact caused by the injudicious use of quinine, even—I am sorry to say—by some of our very best men in the medical profession.

How many eye and ear troubles are looked upon by the average physician, and even some aurists and oculists, without any regard whatever to quinine as even capable of producing such misfortunes. A general practitioner of medicine, or an oculist and

aurist, let him be ever so well qualified and authorized, without regard to "race or previous condition," whether German, Jew or Gentile, if he does not recognize quinine as even capable of doing harm to so delicate an organ as the eye and ear, will surely not look for, and hence most likely not find, cases of defective sight and hearing due, in whole or in part, to effects of quinine.

I may feel the importance of the subject of the POISONOUS EFFECTS of quinine too keenly, but if so, I hope by throwing the question into the Association with all the force in my power, to raise such discussion as will likely better inform me and perhaps some others.

Granting the great importance of the use of quinine by the stomach, as insisted upon by our honored medical authors, to wit: Prof. Bartholow, as above quoted, and also many others, how much *more* important it would be, used subcutaneously, is simply beyond my capacity to estimate, especially since we now have a preparation so entirely free from danger of producing abscesses, when carefully handled. Hypodermatically used, we have *positive* evidence as to *where* it is, hence our observations as to its good and bad effects are of some real value, such as cannot be had by any other mode of using it yet brought to light.

During the first two years of my experience with the hypodermatic injection used in the treatment of the fever cases herein detailed, I did not produce a single abscess. Up to this time I had my solutions prepared at a drug store, but these solutions would not keep well, spoiling more or less rapidly by the development of the penicilium, and an increasing tendency with the age of the solution for the salts to precipitate and perhaps some chemical changes also. I then carried the salts in definite quantities and made extemporaneous solutions, by adding water only sufficient with heat at about 100°. With this I evidently produced some splendid specimens of abscess. I then changed my tactics again, and began making my extemporaneous solutions not so concentrated, say 15 grains of the salt of quinine to at least 20 minims, since which time I have not had an abscess from its use, *i. e.*, when I could reasonably control my patients until time for inflammatory processes not to be expected; e. g., not long ago I saw a man about sixty years old who had been "chilling," as he said, about every two weeks. On the day of my visit, which was Sunday, he had had a chill in the morning, during which he was not apparently much sick, as his wife said, but was somewhat delirious, and went to church in spite of his family, and while there had "a fit or fainting spell, one or the other," and had to be carried home by force. When I saw him he was more or less delirious, with a temperature of 105°, I gave him hypodermatically, bimuriate of quinine and urea gr. viiss, sulphate of morphine gr. $\frac{1}{3}$, sulphate of atropine gr. $\frac{1}{75}$, in water q. s.. I then advised that he would likely need some further attention from some physician, but any way, if he seemed to do ever so well, he had better remain in and take good care of himself, and especially his arm where I had injected the medicine. But he worked in his blacksmith shop the two following days, and on the third hunted me up to abuse me for making his arm so sore that he could not work. In about a week later, he had his arm lanced, the physician operating expecting to get pus, but only got some nearly clear serum.

From the use of this hypodermatic treatment, I am sorry to say, many of my professional friends and neighbors have had ugly abscesses to contend with. Of course, in such cases they were willing to call it "Talley's treatment," especially if they produced an ugly abscess on some handsome, or expected to be handsome, arm. In reply to this, I want to say in a friendly way that in all such cases the patient, in my judgment, needed a physician to begin with.

The important details in making a hypodermatic injection are too many to be given in a paper like this. I have for many years made hypodermatic injections as *deep* and as *slowly* and as *little* at *one point* as possible, for the following, as I think, very particular advantages over the usual method: 1. It gives less pain; 2. It takes effect sooner; 3. It is not so likely to produce abscess; 4. There is comparatively no danger of injecting more than a few drops directly into a blood vessel, an accident that we all want to avoid. This fourth advantage I try to obtain by first introducing the syringe needle as deeply as I well can; then I throw out one or two minims at different points as I very slowly and cautiously withdraw the needle.

In reviewing my paper on this subject, as read before the Texas State Medical Association in April, 1884, *The Texas Courier-Record of Medicine*, Vol. II., No. 1, page 61, says, in referring to my manner of using the hypodermatic syringe: "En-myonic would be the correct name for it, not hypodermic." Like the reviewer, in part, I now do not think the word hypodermic the proper one to use, hence no longer use it. In Prof. Bar-

tholow's "Hypodermatic Medication," pages 30 to 60, he says: "This word hypodermic is condemned by all scholars, who are unanimous that the term should be in accordance with the rules of construction—hypodermatic." That eminent philologist and oriental scholar, Mr. Fitzedward Hall, D. C. L., assures me that under no circumstances is the word hypodermic allowable. * * * He (Prof. Bartholow) further says: "By this" (hypodermatic) "method the medicament is introduced beneath the skin, usually into the subcutaneous areolar tissue, *but also into the muscles*" (italics mine.) Now I think that in all candor the name "enmyonic" for this operation is the least appropriate of any yet proposed.

I want just here to call attention to the fact that in the paper of mine above referred to I *never once intimated* that I confined my injections to the muscles. In the same review just above referred to it is said: "We cannot understand how a preparation of this kind which contains not quite two-thirds of quinine in the dose administered, would be any better than an extemporaneous preparation of a solution of quinine in dilute muriatic acid."

In reply to this, just let me call attention to the fact that it requires 1600 parts of water at 59° Fahr. to dissolve one of quinine. While it is freely soluble in dilute acids, it only requires a little common sense to enable one to "understand how a preparation" of bimuriate of quinine and urea, *which is soluble in equal parts of water*, is better than the alkaloid quinine which is *soluble in not less than* 1600 *parts of water*.

Now, there seems to be a great difference of opinion (a professional difficulty, if you please) between the editor of the *Texas Courier-Record of Medicine*—as in this paper above referred to—as well as other medical gentlemen and myself. I plead "not guilty," and submit the case "to the jury."

Now, since I have raised the subject of the hypodermatic use of bimuriate of quinine and urea, I hope to hear the experience of others in the use of this preparation of quinine (with or without the preparations of atropine and morphine), as compared to others in general use the world over. In the use of quinine in any way for any malarial trouble, I have for several years nearly always used morphine and atropine combined with it, for reasons I cannot here well give without making this paper entirely too long.

If I am not very much deceived, this preparation of quinine, to wit, *quinia bimuriatica carbomidata*, is the best yet on record for use in *any way*, and for *any disease*, for which quinine in any form is at all useful, and for reasons apparent to any thinking medical man who is at all familiar with it. I know the great tendency in our profession to to ride medical hobbies, and sometimes without reason or mercy; and I hence have had an eye to this professional weakness, and tried to avoid it in my experience with this particular remedy.

PRACTICAL NOTES ON THE CARE OF THE RECENTLY DELIVERED PUERPERAL WOMAN.

BY EDWARD P. DAVIS, M. D.,

Of Philadelphia.

In the present age of scientific obstetrics it is possible that attention is given so constantly to the great things of the law, that its minor matters are a little neglected; and hence the following notes may prove of interest.

Let us suppose that delivery has been successfully accomplished, and without laceration requiring sutures or *serre-fines*. There remain, then, no conditions requiring especial restraint of the patient, and, supposing the doctor and his helper to have been clean and careful, the dangers of blood-poisoning are at their minimum. Before leaving his patient the doctor must decide upon the amount of interference which he will allow from the patient's attendants, and his own duties regarding the giving of douches, personal inspection of the genitals, the use of napkins, pads, binders, and the many points which his own mind, or the questions of the attendants, will suggest.

As soon after birth as convenient a thorough inspection of the mother should be made; by palpating the uterus through the abdomen, by vaginal touch, and without hesitation, if needed, by sight. It is not advisable to introduce the fingers or thumb into the rectum, for that orifice is not naturally a genital aperture, and any laceration should be appreciated by vaginal touch or inspection after separating the labia. When the uterus has firmly contracted, and hemorrhage has become only a slight serous oozing, and the pulse and general condition of the mother show that nature's equilibrium has been largely attained, the physician should carefully syringe out the vagina to remove any clots which may be present. A tube of considerable calibre, whose curve is that of

the vagina, and whose apertures are punched from without inwards, and are on the sides only, should be used. Such a tube will give no direct, forcible jet liable to enter the os uteri and do violence; the fluid strikes the sides of the vagina, and not the os uteri and cervix directly, and creates a douche current which readily returns; the best material for such tubes is glass. The syringe should be a fountain syringe; its elevation above the patient's bed sufficient to give a current of moderate force only; the tube should not be inserted until full of fluid and empty of air; the fluid used should be sufficient in amount to thoroughly cleanse the vagina, and its temperature high enough to be comfortable to the patient.

The fluid used may be carbolic acid solution 2 per cent.; thymol 1 to 1000; corrosive sublimate 1 to 4000; if none of these are available, boiled water should be taken.

If inspection has revealed a considerable number of fissures in the mucous membrane of the vagina, which cannot be said to be lacerations to be sutured, but which will become ulcers, a convenient dressing for them will be an adhesive antiseptic powder, sprinkled or blown by an insufflator upon the parts. Such powders are iodoform, salicylic acid, sub-iodide of bismuth, bromic acid, and others. One application of such powder fairly will be sufficient in an ordinary case; a simple rubber bulb may be filled with powder and a small glass or wooden tube used as a nozzle; care must be taken, as in the douche, not to inject air. Nature's occlusion dressing is a scab or crust; the powder, clinging to the abraded surface, answers a similar protective purpose, and the writer has often seen puerperal abrasions continue covered until healed in cases where vaginal irrigation had become needful.

The external genitals should be thoroughly washed with tar soap, or castile soap and warm water; douched with the antiseptic fluid used, and dried with clean cotton which has not been touched during labor.

A binder, while not needed by women whose uteri undergo successful involution and whose abdominal muscles are strong, is not injurious. If it causes doctor or nurse to neglect to diagnose a relaxed uterus, by abdominal palpation, it is a decided injury. If the physician has confidence that any cloth placed over the vulva to receive the lochia will be removed and destroyed frequently enough for the safety of the mother, he may order such a bandage or napkin. If the ignorance of obstinacy of the attendants renders this unsafe it will be far better to allow the lochia to escape upon an old, but clean, folded shirt placed beneath the patient's hips: it would probably be more frequently renewed than a napkin. Of antiseptic bandages for the vulva, the following is simple: a strip of cheese cloth or clean old linen, 18 inches long and 12 wide; a layer of borated or salicylated cotton, 1½ inches thick and long enough to cover the vulva, is included in the bandage which is folded longitudinally once, being then 6 inches wide. This bandage is "run across" at the ends and sides with needle and thread, and pinned with four safety-pins to the binder, one pin at each corner: these should be renewed three times daily, and burned after using. Considerable comfort can be given to the patient by the use of pads one yard square, made of cheese cloth enclosing cotton batting 1½ inches thick, the corners tied with cotton yarn: they may be placed beneath the woman in place of draw sheets, when the vulvar bandage is used; they wash well and add to the comfort of the patient.

Shall vaginal injections be given? Not without positive indications. As long as the patient presents no signs and symptoms of an abnormal lying-in condition, she should not be disturbed. The external genitals should be cleansed three times daily, the most scrupulous cleanliness observed in all which pertains to the patient. The child should nurse as soon as the mother has rested and reacted after labor. The nipples should have been carefully washed during pregnancy, to prevent the accumulation and drying of milk; if this simple precaution has been observed the ducts will generally be found pervious. A lotion, tonic and astringent, and free from injurious metals, should be used in bathing the nipples after nursing. To prevent mastitis there are no better means than cleanliness and disinfecting the nipples, and a broad figure-of-eight bandage supporting the breasts and compressing them.

That food most easily borne by the patient, to which the patient is accustomed, and which is craved, is best.

Upon any irritation about the pelvis, before the usual three days have elapsed, after which a laxative is given, an enema of warm soap-suds and castor oil, administered gently, will be of great service.

After-pains should suggest partial relaxation of the uterus, and the presence of clots in the cervix and vagina. Uterine massage through the abdominal walls, and the removal of such clots by the physician, should the pains be severe, are indicated.

The usual minor pains are relieved by warm applications externally or chloral, the uterus extruding the clots. The catheter should be passed, when needed, under the advantage of light, and strict precautions of cleanliness observed before and afterwards. An S-shaped catheter, in which the space between the fenestra and the tip is solid, to prevent the accumulation of pus, is best and most easily disinfected.

These notes do not attempt to deal with the complications of the puerperal state, but with the care of a normal patient immediately after labor. If much attention seems to be given to minutiæ, it is because "an ounce of prevention is worth a pound of cure."

AN EFFECTIVE TREATMENT OF HIP-JOINT DISEASE.

BY B. M. GRIFFITH, M. D.,

Of Springfield, Ills.

Mr. A. A. B., age 32 years, Canadian parentage. About 4 years ago received a severe fall upon the right hip, when alighting from a moving train. To all appearances he soon recovered from the immediate effects of this injury. About two years afterwards his hip joint commenced paining him upon excessive exercise or fatiguing use of the limb, and in the course of another year he complained of pain in the knee joint, especially on the inner aspect of the joint. This was the history of the case when I first saw it in August, 1886. The right limb was apparently three-fourths of an inch longer than its fellow, and the foot slightly everted. He complained of excessive fatigue in the joint on walking, especially if the ground was rough, and if he accidentally stubbed his toe the pain in the joint was quite severe. Upon sneezing or coughing, he would instinctively seize the affected limb in order to lessen the pain caused thereby. No hereditary taint was discovered by examination of the patient's history. The general health was quite good. On manipulating the limb the hip joint was found rather sensitive; inversion was limited. When lying on the back patient was unable to place heel of right foot on the toes of the left; the pelvis was also tipped considerably, and the pain was quite marked when the limbs were fully extended in this position. The pain was lessened by flexing the thigh on the abdomen at an angle of about 20°, and slightly everting the foot, and by so doing placing the pelvis flat on the floor. At no time was pain produced by striking the heel of the foot while the limb was extended. The plan of treatment entered upon was one suggested to the patient by Prof. Gunn, of Chicago, *i. e.*, the application of a plaster of Paris cast to the pelvis, and thereby immobilizing the hip-joint. The cast was applied as far up the body as the xiphoid cartilage, and extended down the affected limb to the knee, making it especially strong in the groin. The cast was applied by having the patient stand on a stool, and the limb somewhat advanced and slightly everted, thereby placing the limb in a comfortable position. The patient was afterwards placed on a canvas cot, and a double inclined plane with a light weight used. In this position he was entirely comfortable, and commenced improving from the start—cod-liver oil and comp. syrup wheat phosphates being the only medication. Patient was kept in the cot for twelve weeks, when the cast was removed. The patient complained terribly of muscular soreness for several days. The limb can now be moved in all directions, flexion and adduction being slightly compromised. No pain in either the knee or hip joints. The movements, while slightly limited, are more powerful than formerly, and are getting stronger. The pelvis is also improved in position. It has been four months since the cast was removed, and neither pain nor any of the old sensations have been felt in the joints.

This case I offer as an illustration of a most effective method of treating hip-joint troubles when seen under such conditions, believing it more efficacious than the use of braces.

MEDICAL SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated meeting, April 27, 1887. H. Augustus Wilson, M. D., in the chair.

Dr. Charles H. Burnett read a paper on

Ear Trumpets.

There are three reasons, he said, why the deaf should use ear-trumpets:

1. In order to aid the hearing.
2. To improve the hearing.
3. For the convenience and comfort of those conversing with the very deaf.

1. When a person becomes very deaf in both ears, some resort to an artificial aid of hearing must be made. So long as one ear remains fairly good, patients will not use an

ear-trumpet for the deaf ear. But when ordinary tones near the ears are heard either very imperfectly, or not at all, the sufferer gladly resorts to some form of ear-trumpet. Most of these are unpleasant and imperfect aids, from their disagreeable resonance, and poor conducting powers. They also bruise the meatus, in most cases being made with an ear-piece which fits into the mouth of the auditory canal. These discomforts and imperfections, in the average ear-trumpets of all forms heretofore invented, added to the natural indisposition to employ an ear-trumpet because of its conspicuousness, have in most cases led to an early abandonment, or a partial use at least, of such an instrument.

The cause of ordinary deafness is, in most cases, a catarrhal thickening of the mucous membrane over the ossicles and the inner surface of the membrana tympani, leading to more or less ankylosis in these parts. Passive motion overcomes in them, to a greater or less extent, the immobility induced by this sclerotic process, as it does elsewhere in the osseous and muscular system. The form of passive motion which acts most naturally on the ossicula auditus and their joints, is sound. If, therefore, sound-waves are concentrated in more than usual quantity or vigor upon the stiffened membrana and the ossicles, as by means of an ear-trumpet, hearing is induced, if the auditory nerve is unimpaired. If the latter is impaired, no form of ear-trumpet will be of use.

2. Not only does such a form of passive motion give immediate relief to the deafness in most cases, but such a form of passive motion, acting frequently and systematically upon the ear, prevents further ankylosis in the conductors, and fatty degeneration of the auditory nerve from desuetude. This, of course, tends to a permanent improvement of the hearing, and, in some instances, patients come to hear at last without a trumpet. If such a force were brought to bear early in cases of deafness from ankylosis in the ossicula, the defects in hearing could, in most cases, be arrested, and, to some extent, removed. This form of aid to hearing has its happiest results in very deaf children, in whom the loss of hearing often entails loss of speech, if they have already learned it. If they have not learned to talk, and their deafness depends on catarrhal disease in the middle ear, and not on a lesion of the acoustic nerve, the use of a good ear-trumpet will rescue them from entire deaf-dumbness.

3. The convenience and comfort of those who communicate with the deaf by means of a trumpet are not the prime, though important considerations. For, if this mode of conversation is rendered difficult by reason of the imperfect ear-trumpet at command, it will not be readily or willingly employed, and, in the case of children, therefore, not enough will be said to them to improve their hearing or to teach them speech.

The most useful ear-trumpets yet presented to his notice are those of Mr. Maloney, who exhibits them here to-night. They are not only useful as conductors of sound, succeeding where other forms fail, but they do not fit into the meatus. They are held to the ear, the aural end of the instrument being supplied with a disk, and not a tip for the meatus. This does away with bruising the canal, or exciting furuncles in it, so common in the employment of the form heretofore in use. They have been devised in a scientific manner, and introduced to the profession on their own merits. The best results, or the most signal ones, have been obtained by the so-called silent instrument. This is simply because it is the most powerful, and hence renders most aid to the very deaf, the only people who are really willing to use any instrument. The smaller instruments are just as good for those not very deaf, and, if used by such patients, would aid in the retention of hearing, and tend to cure their hardness of hearing, as he has shown. But the less afflicted class seem unwilling to use any form of ear-trumpet. All ear-trumpets of any value must possess some size in order to contain a column of air sufficient to impress the drum. They must be larger than the auricle with which the patient is already supplied. Hence, all invisible appliances, so called, are self-evidently good for nothing.

Mr. J. A. Maloney, of Washington, said that he commenced his labors in "Aural Mechanics" with a mode of procedure as follows:

1st. To develop instruments as far as he could to meet the various phases of defective audition.

2d. To construct the instruments to give satisfactory results without entering the auditory canal.

3d. To use artificial drums or membranes to guard against impact of air upon the "membrana tympani," and prevent reverberation, so common in all the old forms of instruments. He decided that a scientific instrument should possess these three essential qualities: it should be large enough to be of practical value; it should augment sounds; but with such augmentation the "timbre" or quality of sound should be preserved.

We are all aware that the membrana tympani, unlike other stretched membranes, responds to all vibratory motions within a certain limit, whether they are in the form of noise or of composite tones, transmitting through the intermediate agencies of the middle and inner ear, to the nerve of hearing, auditory sensations, Could a stretched membrane be arranged, so closely imitating in function the one given to man as to show how beautiful are the harmonies of nature?

After experimenting twelve months, he adopted the form of membrane which he presented. The reason for its adoption came about in this way. In the early stage of his experiments he invariably found a lack of clearness of tone, until one day the thought occurred to him that he could secure uniformity of tension by clamping the membrane between two rings. When this was done he found it a great improvement over all other methods, and consequently adopted it after thorough tests. Even after obtaining good results, he could not but feel that there must be some other result produced by the rings than that of maintaining a uniform tension of the membrane. He found that while the membrane was upon the stretcher-frame, with the rings glued upon each side of the membrane, like any other membrane, it would be thrown into sympathetic vibrations by tones corresponding to its fundamental; *but that when cut from the frame*, and dependent for its tension upon the two rings alone, it would not respond to a tone corresponding to its fundamental. Now it has been thought that the last named feature exhibited by the membrana tympani was produced by its union with the auditory ossicles. But may it not be due to two facts? 1. That the margin is thickened. 2. That the middle layer, or "substantia propria," is fixed to a ring of bone.

His membrane describes a central vertical line between the two rings acting as clamps, and the rings themselves represent the ring of bone to which the middle layer, or "substantia propria," of the membrana tympani is attached. In the construction of the instrument, the fact must be borne in mind that it must be arranged to suit and compensate for the defect of hearing. 1. Arrange for high tones, if the defect is in that direction; or for low tones, if the defect is in that direction. 2. The augmentation and clearness must be to the extent that the person will hear every word spoken, instead of a word here and there, as heretofore, which involves a severe mental strain to construct the incomplete sentences.

Dr. S. S. Cohen said he had the pleasure of seeing some time ago a demonstration of these instruments in the case of some patients of Dr. J. Solis Cohen, and they acted very satisfactorily. A letter was received some time ago from Dr. Lacharriere, of Paris, the eminent physician in charge of the National Institution for Deaf-Mutes, inquiring as to the truth of reports that in certain institations in this country, especially in New York, ear-trumpets were being used in the instruction of so-called deaf-mutes, and that it had been found that a gratifying proportion of children thought to be totally deaf, reacquired in this way a certain degree of hearing power. After some correspondence, he learned that Mr. Currier, Professor of Articulation in the Deaf-mute Institution at Washington Heights, New York, had used an instrument different in construction from that of Mr. Maloney, with good results. He published accounts of them in the *Annals of the Deaf and Dumb* for January and for October, 1885. He reports a number of cases that have acquired the power to carry on conversation. Mr. Currier uses what is termed the "conical conversation tube," attaching two mouthpieces and tubes to a single earpiece, in order that a patient may hear his own voice as well as that of the instructor. His system of instruction to reawaken so-called "latent hearing" is ingenious, and from his reported cases, apparently quite successful. If Mr. Maloney's earpiece were attached to Mr. Currier's double tube, it might be found still better.

Dr. C. Wirgmann asked if there were any liability for the rubber disk to get out of order.

Mr. Maloney said with reference to the durability of the rubber, that it was a protective coating. During the past nine months he exposed them to varying changes of temperature without any apparent effect. If the membrane should get out of order it can easily be replaced. He had never had his attention called to the instrument of Mr. Currier until the matter was mentioned by Dr. Cohen this evening. He finds that his instrument is open at both ends. In speaking of what he terms No. 3, or "silent," instrument, he neglected to state that it is closed at the end nearest the ear. The object of this is to prevent the impact of the air on the drum of the ear. Such impact has a tendency to destroy the clearness of the tone. With his instrument, the only impact on the "membrana tympani" is that of the column of air in the auditory canal between the membrane of the instrument and

the drum of the ear, thereby developing *true auditory sensations* which cannot be produced by instruments open at both ends.

While he has done something in the way of testing those supposed to be entirely deaf, he is not prepared, without his notes, to speak on this subject, because he has not yet finished the line of tests marked out. He can say, however, that he has made tests in two cases supposed to be totally deaf and dumb. One was a man, forty-two years of age, and deaf from childhood. He made him hear on both sides *noise only*, for the percipient functions had never (as in such cases) been trained or educated. The other was a boy, eleven years of age, supposed to hear very slightly on one side only. Upon making tests he found he could hear on both sides, *noise only*, for the same reason as mentioned in the foregoing case. When he completes the line of tests marked out he will be glad to present the results to the Society.

Dr. C. H. Burnett said that the question of so-called latent hearing in deaf-mutes is, of course, very important. In one sense, there is no such thing as latent hearing. Without doubt, many deaf children lose the power of talking if they have previously acquired it, or fail to learn to speak on account of their inability to hear. In the case of a graduate of two deaf-mute colleges, the man's wife discovered that he could hear to a certain extent, and by systematically talking to him, he acquired the power of hearing an ordinary tone of voice while in an adjoining room. This case was reported to him by Mr. Graham Bell, of Washington. In most cases, deafness in due to ankylosis, and the use of an ear-trumpet is simply another application of the movement cure.

He has himself seen a child a little over two years of age, just learning to talk, lose its hearing to a marked degree. By persistent teaching on the part of the mother the hearing was much improved, and the child was rescued from a condition of deaf-dumbness. The child is now twelve or thirteen years old, and while the hearing is not perfect, she is far from being a deaf-mute. Many deaf mutes can hear something. It is very onerous for even a parent to exercise the hearing by the unaided voice, but with an instrument like those of Mr. Maloney's, the parent may be induced to undertake the task.

NEW YORK ACADEMY OF MEDICINE.

Regular meeting, April 7, 1887.

A. Jacobi, M. D., President, in the chair.

On the Proper Selection of Ether or Chloroform as an Anæsthetic.

Dr. A. G. Gerster read a paper with this title, in which he said both chloroform and ether are dangerous, but in general chloroform is the more so. It is the more powerful agent, and should be administered cautiously, and in properly selected cases. But this is not sufficient ground for its unqualified condemnation. Consciousness being restored there is no secondary danger from chloroform. This can not be said of ether, for numerous cases of nephritis and pneumonia have followed its use. The contraindications to ether, in his opinion, were Bright's disease and bronchitis. In certain operations its effects were unsatisfactory, as in herniotomy and operations involving the peritoneum and deep tumors in the vicinity of large vessels. Certain patients, especially those addicted to the use of alcohol, sometimes only in a moderate degree, took ether badly, and were unduly affected by collections of mucus in the bronchi. Some patients could not be satisfactorily anæsthetized by ether, and here, chloroform being substituted, complete anæsthesia followed. Ether should not be given in the large quantities and careless manner so frequently seen. He employed Ormsby's inhaler, which he regarded as the best; a minimum of ether being required, the patient could be quickly restored.

Cases were cited in which nephritis or pneumonia had followed the use of ether, in some the result being fatal.

The only contraindication to the use of chloroform was a weak heart from whatever cause. Patients who feared the operation, or who were nervously depressed, were more likely to be badly affected by chloroform. A weak heart also rendered ether more dangerous, but chloroform was more so.

Dr. H. Knapp sent a letter, giving the result of his experience with ether and chloroform. Prior to 1874 he had employed chloroform in over three thousand cases. There was no fatal result, but in many unpleasant effects. He had seen fatal results in Berlin and Vienna, and was in constant dread. Since 1874 he had used ether in all classes of cases, administering it according to the so-called choking plan. In a few he had to interrupt the narcosis temporarily. The secondary effects had not been worse than from chloroform. He thought it was safer than chloroform, and as manageable or more so.

Dr. R. F. Weir thought the presence of kidney disease should make us more cautious in the use of ether, but he would not substi-

tute for it chloroform. The pneumonia following ether was due often to exposure of the patient, especially in applying wet cloths, formerly by the spray, etc. He knew of only four deaths from ether in the New York Hospital.

Dr. L. A. Sayre used chloroform. He preferred it because it is more agreeable; it is more speedy in its effects; it does not produce spasmodic muscular contraction; it is not followed by bad after effects—as vomiting, trouble with the respiratory organs and kidneys, etc. To give ether or chloroform freely mixed with air, requiring large quantities, and causing the patient to struggle, was wrong. He gave chloroform by his inhaler, requiring only twenty or thirty drops to produce anæsthesia after a few inhalations. Administered in this way, should the heart cease to act it could be restored by a few artificial respirations. This was not the case when a large quantity had been inhaled by the ordinary method of administering it.

Dr. W. Gill Wylie had within the past two months had two deaths from ether, one from Bright's disease caused by it, the other from suffocation an hour after herniotomy. He had never before had any difficulty. He knew of another death from it near where he performed his operation with the fatal result from the ether. Generally ether was safer than chloroform. But chloroform was employed in the lying-in chamber and in children; he would also give it in many cases of lung and kidney troubles.

Dr. Wyeth, Dr. Abbe, and Dr. Thallon agreed with Dr. Weir that the presence of kidney disease should render us more cautious in the use of ether, but it should not necessarily contraindicate its use. Dr. Mundé considered ether the safer anæsthetic, but both it and chloroform were dangerous, and should be administered by skilled hands in a cautious way. Dr. Amidon would precede the administration of ether by atropia or a preparation of belladonna, to lessen bronchial secretion.

Periscope.

How Bright's Disease Comes About.

In a paper thus entitled in the *Medical Register*, Dr. J. Milner Fothergill writes as follows:

The hard, keen brain-toiler is liable to derange his viscera, and his liver reverts to the uric acid formation, as years roll on. Not only that, but he begets children with congenitally insufficient livers, *the innate weakness of Murchison*. In some cases urates are seen in childhood, and vesical calculus is not infrequent in babies. More commonly, however, it begins to show itself after puberty. A lady of this type will present the following characteristics and symptoms: She is a bright, sensitive, high-spirited, and usually high-souled, unselfish creature; light in the bone, commonly petite, muscles not large, but firm, and when she shakes hands her grip is that of decision, as are the tones of her voice; her features are regular and mobile, often small; her susceptibilities are keen, and so are her special senses. She is capable of great devotion, and in her earnestness is usually self-forgetful; she is emotional, but not demonstrative, and is a distinct neurotic. As to her complaint, she has indigestion accompanied by acidity and flatulence, often alternating; commonly some constipation; she is liable to attacks of hemicrania, or migraine, or "face-ache," as she calls it, usually unilateral and on the right side, accompanied by sparks or "dazzles," often ending in vomiting; and these migrainous attacks are accompanied by great vesical irritability, and constant call to make water; she has fits of palpitation, and at other times failure of the heart's action, differing from syncope in that there is no loss of consciousness, and she feels unutterable sensations, of which the expression of the eye mutely tells. She constantly has sediments in her water, though a small eater, and especially avoiding animal food. She has an insufficient liver, which Dame Nature protects by a small, fastidious appetite, and a dainty palate, despite which it reverts to the uric acid formation. She is a typical instance of the adage, "The sword will wear out the scabbard." She has no mercy upon her body, and her complaint is that it is very hard that she cannot do as others do. If she goes to the theatre or concert, she so thoroughly enjoys it all that probably she is in bed next day with migraine. Her old nurse speaks of her as "all up and down"—either volatile and gay, or irritable and depressed. Somatically these neurotics of the Arab type are the greyhounds of the human

race—light, active, and nimble; but psychically greatly superior to these canine representatives.

She is to be found everywhere, but most markedly in towns. She is a charming patient; but rarely yields flattering results of treatment. She is acute, and capable of taking care of any one but herself. She is in my experience commonly an American lady; and in most instances tells of the energetic, long-sustained, and usually successful efforts of her father. "The fathers have eaten sour grapes, and the children's teeth are set on edge." Her father carried on severe mental toil at the expense of his viscera; his daughter comes into the world framed on his pattern. In both we find reversion to the uric acid formation, and, of course, with that the whole consequences thereof.

And one of the direct outcomes of uric acid in excess in the blood is interstitial nephritis, commonly termed "Chronic Bright's Disease."

Removal of Broken India Rubber Catheter From the Urethra.

John Small, L.R.C.S., of Geelong, writes as follows to the *Australian Medical Journal* of March 15, 1887:

At 1 a. m. on November 10, 1886, I was called to a case of retention of urine in a man of sixty years. Thirty ounces of urine were withdrawn through a silver catheter (No. 12), without difficulty.

Next day some more urine was drawn off, and a pure rubber soft catheter (Jacques' No. 9) was given to the patient, with instructions to use it regularly every eight hours.

On the night of the 28th November, I found him waiting in my consulting room, in considerable pain, and he gave the following account: At 9 a. m. that day, he had passed the catheter as usual, and had withdrawn an average quantity of clear urine, the bladder he noticed beginning to contract well. At 6 p. m. he tried to pass the catheter again, but found some obstruction, which he attempted to overcome by forcing the instrument onwards, but when it had disappeared into the urethra (without any urine passing through) he began to be alarmed, and tried to withdraw the catheter, and failing, pulled more strongly, with the result of leaving a large portion of the instrument in the urethra, only five or six inches coming away. He now said that he felt it was in his bladder.

Using a No. 6 silver catheter as a probe, I could feel the missing part, a little in front of the triangular ligament, and by exerting deep pressure into the perinæum, a well defined lump could be recognized.

Treatment.—After placing the patient in the erect position resting against a table, and warning him to cry out immediately he felt any pain, I proceeded with a pair of œsophageal forceps (curved something like a prostatic catheter, and opening vertically) to try and extract. After several failures, the forceps kept their grip, and the catheter was drawn several inches forward. The forceps then slipped, and with no other forceps could I get it further than one inch from the meatus. There was now some hæmorrhage. After carefully manipulating through the skin, I decided that the catheter was firmly doubled on itself, forming too large a mass, plus forceps, to pass through the canal. After waiting a few seconds, I passed a properly bent probe into the urethra, and by careful manipulation, causing a little pain, got it through. Extraction was then easy. The patient was then relieved by having his urine drawn off through a No. 6 soft catheter, and he then insisted upon walking home.

Nomenclature of Pathogenic Micro-Organisms, According to the Accepted Recent Definitions of Dr. J. Schrœter.

Micrococcus vaccinæ (Cohn), the active portion of vaccine lymph; micrococcus decalvans (Cohn), produces baldness; streptococcus erysipelatis (Koch), induces erysipelas; streptococcus diptheriticus, active in diphtheria; hyalococcus pneumoniæ, present in croupous pneumonia; hyalococcus Beinzii, causes the gregarina of hair; bacillus anthracis (Cohn), produces anthrax; bacillus tuberculosis (Koch), in phthisis; bacillus lepræ (Hansen), in leprosy; bacillus syphilitidis (Lustgarten), in syphilis; bacillus typhis (Eberth), in typhoid fever; microspora comma (Koch), induces Asiatic cholera; microspora Finkleri (Koch), present in cholera nostras; cladothrix Fœrsteri (Cohn), found in disease of the lachrymal ducts.

Biniodide of Mercury.

The great drawback of the employment of the biniodide of mercury as an external application consists in its insolubility. M. Méhn, Member of the Academy of Medicine in the Pharmaceutical Section, has overcome this difficulty by recommending the salt to be rubbed up with castor oil,

which completely dissolves it. A solution of one part of the salt to fifty parts of castor oil does not become cloudy. This solution is sufficient to satisfy the exigencies of therapeutics. The addition of iodide of potassium increases the solubility of the biniodide of mercury in castor oil.—*Paris Correspondent of the American Practitioner and News.*

Antifebrin.

J. K. Murray, M. B., presents the following cases showing the advantage of antifebrin over other antipyretics in the *Lancet* of April 23, 1887:

Case 1. J. B., aged 3; meningitis, with a temperature ranging from 102° to 105.4° F. Three-grain doses were at first tried in the forenoon. The temperature fell from 105° to 101.4° during the first two days, but on the third evening 104.4° was registered. Five grains were then given every three hours, and the temperature fell to 99.4° after two doses, and remained thereabouts. When two doses were omitted the temperature rose again.

Case 2. A. V., aged 2; broncho-pneumonia, with temperature from 103° to 105° F. At first three-grain doses were given every three hours, and for four days this kept the temperature below 100°. On the fifth day the temperature rose repeatedly above 102°, so five grains were given every three hours, and the temperature fell to 99.4°, and remained at that point.

Case 3. M. L., aged 25; pyelo-nephritis. Fifteen-grain doses were used. The temperature fell to 99° within one hour and a half, and remained there for ten or twelve hours. I had the temperature taken every three hours, and whenever 101° was registered, fifteen-grains were given. Quinine in ten-grain doses was tried under the same conditions. The temperature fell about 2.4°, but rose to 104°, and sometimes 104.8°, within six or seven hours.

Remarks.—Antifebrin seems much more powerful than quinine, kairin, or antipyrin. It equals antipyrin in the duration of its effects, and in this respect surpasses quinine or kairin. It is only excelled in the quickness of its action by the external application of cold. Its effects are evident within an hour, and they last from ten to twelve hours when a full dose has been administered. When administered for a long time, the dose must be increased. It produces profuse sweating and redness of the cheeks; it diminishes the pulse-rate, and distinctly increases arterial tension. I found no depressing effects follow its administration even when full doses were given. Antipyretics belong to two great classes, namely, those which diminish tissue metabolism; and, secondly, those which increase the loss of heat. From the sweating it produces and the rise in arterial tension, one might conclude that antifebrin belongs to the second classas well as to the first one. This might explain the quickness of its action, as antipyretics of the second class act more speedily than those which diminish tissue metabolism.

A Case of Hermaphroditism Unrecognized for Sixty-Nine Years.

Last year, a man aged 69 died after the reduction of a "labial" hernia in the Charité Hospital, Paris. At the necropsy it was found that "this individual, a woman for sixty-nine years, was a man." He had always believed himself to be a woman, and had dressed and lived as such. There was, however, a history of masculine sexual propensities, and he liked to do heavy manual work, which his powerful, muscular frame enabled him to perform. He was often morose and suspicious. He was never married. Messrs. Pozzi and Grattery describe his case in the *Progrès Médical*, of April 16. There was hair on the chin and lips, indeed the patient shaved regularly, but none on the cheek, chest, extremities, or along the line between the umbilicus and pubes. There were labia, which did not go so far back as in the female. The right labium majus contained the right testicle and a hernial sac. The labium minora formed the prepuce and the frænum of the glans penis, which was large, bifid below, and provided with a corona; the corpus cavernosum was single, and attached to the deep perineal fascia, and not to the pubic arch. The groove which ran along the under surface of the bifid glans was continued along the vestibule to the orifice of the meatus urinarius; the groove bore crypts like those which are found in the male urethra. There was a vulvar pouch one inch and a half deep, the perineal raphé was not quite four-fifths of an inch long. Below the bladder, a fleshy mass received the vasa deferentia in a hollow on its surface. This mass, the uterus masculinus, was hollowed by the vulvar pouch below. The vasa ran through the uterine wall, and beyond it were dilated and irregular for some distance. The left was joined the undescended left testicle, and was pervious. The right did not reach its testicle, but ended as an impervious

cord in the wall of the hernial sac in the labium. The left kidney was atrophied, and contained a calculus. This case was an instance of transverse hermaphroditism, the outer parts being of a female, the inner of male type. The presence of labia and of a vulvar orifice naturally gave rise to the belief that the subject was a woman.

The Management of Post-Partum Hemorrhage.

Dr. Schomberg, of the Lying-in Institution in Christiania, writing on post-partum hemorrhage, states that the number of cases in which this occurred to a serious extent during the years 1876–1884 was 54 out of a total of 2533 labors—*i. e.*, about 2 per cent. of all cases. He appears to have but little faith in ergot for immediate arrest of violent hemorrhage, either administered internally or as ergotine injections. In the case of women subject to hemorrhage, he advises a course of tonic strengthening treatment during pregnancy. When hemorrhage occurs the coagula must be expelled by external manipulation, and then he finds that the most advantageous plan of immediately arresting the flow is to close the os uteri by compression. He refers to Hamilton's paper in the *Edinburgh Medical Journal* for 1850, and to Fasbender's similar plans described in 1869, without apparently any knowledge of Hamilton's previous work. The Norwegian surgeon introduces the fingers of one hand into the vagina, the tips reaching to the anterior fornix, and pressing the anterior lip of the os backwards. The other hand grasps the uterus externally, anteflecting it while the fingers compress it from behind against the fingers of the other hand, the os being thus mechanically closed. Dr. Schomberg is inclined now to prefer cold to hot injections, notwithstanding the great estimation in which the latter are beginning to be held. He warns obstetricians not to administer irritants too freely, as they set up nausea, and this adds to the condition of collapse. He has, however, latterly been in the habit of giving teaspoonful doses of a concentrated solution of common salt with excellent results.

Treatment of Catarrhal Jaundice.

Dr. Gluzinski, writing in a Polish journal, states that in cases of catarrhal jaundice he has found excellent results follow the treatment recommended by Krull, viz., the repeated injection into the bowel of large quantities of cold water. This increases the peristaltic action of the intestines, and removes any mechanical obstacle to the flow of bile. Again, as has been shown by Röhrig and Mosler, who injected large quantities of cold water in dogs, the bile is thus rendered both more liquid and more abundant, so that it more easily overcomes any obstruction. At first water at 59° F., is injected into the bowel until the patient complains of a feeling of distension in the abdomen. He is then made to retain it as long as possible. Most patients manage to retain two litres for from a quarter to half an hour. The next day the enema is repeated, but with water about 4° higher. The temperature is again raised on each succeeding day, but when 72° have been reached no further increase is made. The reason of the increase is that the repeated introduction of cold water is apt to irritate the mucous membrane of the bowel. Altogether four or five enemata are sufficient to produce the desired effect. The increase of the biliary secretion may be judged of by the color of the fæces. Of course, the diet is attended to in order to prevent a recurrence of the affection.

Action of Drugs on Gastric Movements.

Some excellent researches are still in process of conduction by Schütz, on the action of some medicaments on the movements of the stomach. Emetine, tartar emetic, apomorphine, strychnine, in a less degree caffeine, veratrine, chloride of barium, nicotine, and pilocarpine in small doses, act as direct excitants of movements of the stomach, which become spontaneous and of abnormal character. Muscarine directly stimulates the terminal ramifications of nerves in causing generalized contractions of the stomach. Physostigmine, digitaline, scillitine, and helleborine produce an increase in the excitability of the muscular coats in such a fashion that the stomach at a given time is agitated by generalized and prolonged contraction. Actual paralysis of the auto-motor centres has not been observed, but chloral, urethane, morphine, pyrophosphate of zinc, arsenic, as well as nicotine and pilocarpine, in large doses, have caused weakness of the gastric contractions. Paralysis of the terminal branches of the nerves has only been obtained by atropine. Ether and chloroform suppress the excitability of all the innervation apparatus, but only during the time when the stomach is exposed to the direct action of the vapors. During anæsthetic sleep the gastric movements are not influenced.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
C. W. DULLES, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called to the ***QUARTERLY COMPENDIUM,*** which we publish. It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician. It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance for the year.

Address **RANDOLPH & DULLES,**

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

During its twenty-four consecutive years of existence there has been in action a broad and liberal policy governing the conduct of this journal. Those controlling it have fully recognized the value of theory and experiment, and have always presented the latest laboratory bulletins. They have, however, also recognized that the practical test is the crucial test, and have given chief prominence to terse reports of bedside experience. A shrewd, careful and practical observation of cause and effect in the treatment of disease, carries on its face the passport of admission to these columns, no matter whence its source; while on the other hand, the highest professorial title gives no entrance to the REPORTER, if the matter appended have not actual worth.

This journal has maintained an independent attitude on all questions relating to the welfare of the regular medical profession in America. It is the organ of no college, clique or section, and it is the representative of no commercial interest.

These are the attributes which have made the REPORTER a weekly visitor in every town in the Union, and the policy which is here outlined will be vigorously pursued under the present editorial management.

PEPSIN IN THE TREATMENT OF CHRONIC TROPICAL DIARRHŒA.

In a recent number of the *Indian Medical Gazette*, Mr. George Harrison Young reports three cases of chronic diarrhœa which had proved rebellious to the ordinary methods of treatment. In each of these cases the treatment was stopped, and the patient placed on a milk diet, a half-pint being taken every three hours, and 5 grains of pepsin given four times daily. The record of his cases appears to show that great benefit was derived from the use of pepsin. Mr. Young states that he has now used pepsin in a considerable number of cases, and always with success. He claims that this mode of treatment is especially applicable to that form of diarrhœa in which the motions are large and frothy. These cases are due to insufficient digestion and secondary fermentation of the food. When this form of disease becomes established astringents are useless and often even

injurious. Pepsin at once checks the diarrhœa. Only milk diet should be allowed, and the pepsin may be given with the milk. In typhoid fever, the author claims that pepsin, by increasing digestion and assimilation of food, will thereby lessen the diarrhœa and intestinal irritation, and by so doing will diminish the severity of the disease. It is also useful in dysentery occurring in debilitated subjects.

Notes and Comments.

Disinfectants and Their Uses.

Dr. Alfred Carpenter delivered an address at the last monthly meeting of the Association of Public Sanitary Inspectors, on "Theory and Practice as to Disinfection." He urged that sanitary inspectors, who have very great power if they use it carefully, should reason out the grounds of the application of any particular mode of disinfection, rather than give a blind obedience to written orders. With regard to small-pox, he pointed out that germs of living protoplasm in the breath of a patient will take root if immediately transplanted to the membrane of a susceptible person, but if floated about in the air for 100 yards they will lose their vitality. Isolation, with ventilation, as rapidly as possible, is necessary in such cases. For disinfecting the furniture of a house after infectious disease steam is preferable, and he advised all local authorities to provide themselves with the means of applying steam heat. Dr. Carpenter did not recommend carbolic acid as a disinfectant in cases of disease, for it has been found that the acid preserves the dormant germ from decay. This also hold goods of alcohol; the use of spirituous liquors as a protection against the evils of impure water is no protection at all. The same argument applies, though in a minor degree, to sulphurous acid. The best disinfectant is a solution of bichloride of mercury. It requires to be used with care, but it is rapid in its action, and so powerful that a solution of 1 part in 5000 of water will in fifteen minutes destroy every living germ, dormant or otherwise, with which it comes in contact. The best disinfectant for sewers is sulphate of iron. Dr. Carpenter concluded by saying that the lines on which disinfection should be carried out are: Ventilation, aërial disinfection by chlorine or steam, lime washing, washing floors and furniture with solutions of mercuric chloride; steam heat for clothing, furniture, etc.; and sulphate of iron or chloride of lime in adequate quantities for flushing. If these means are effectively applied, infectious diseases will be completely banished from our midst, and any local authority which now allows of their continuance is doing defective work.

Adhesive Plaster.

Dr. Addinell Hewson recently gave a description of a method of preparing adhesive plaster: Bookbinders' paste, which in its pure and clean state is simply a wheaten flour paste, made in a porcelain crock by boiling thoroughly one part of flour in three or four parts of cleanly filtered water, always for twenty minutes, stirring the mixture all that time by a clean, new wooden or bone spatula, is applied by a thin strip of wood directly to the bare, clean integumentary surface of one of the edges which are to be secured, and then one end of a strip of gauze is to be laid on it and rubbed gently and smoothly so that the paste will come through its meshes. It should be applied no nearer the edge of the wound than collodion would be. It dries as quickly as the latter, and has, indeed, the advantage of always drying fast, even on a moist or dampened surface—a property wanting in liquid glass as well as glue, even where expedients have been previously used to dry the parts. When the end of the strip first applied is fixed by the paste, some of the latter is to be put on the other side of the wound, and the gauze strip drawn smoothly across it and pressed on that side, the surgeon watching the contact of the lips as to how well it is secured, rectifying by a probe any irregularity to be seen through the meshes. Sometimes in a long wound it may be advisable to secure the initial extremities of the gauze strips alternately on both sides. On other occasions it may be better to fix them on one side and draw all by their free extremities across, and so get equal amount of traction and tension in that way. The paste, when made strictly according to the directions given, and kept covered in dry place, will not sour, and such paste can be made the vehicle of various kinds of antiseptics and disinfectants. By the addition of a small quantity of corrosive sublimate (one grain to a pint) immediately after it is fully boiled, it effectually prevents the germination and development of various kinds of microbes wherever it may be applied.—*The Polyclinic.*

Absorbent Canton Flannel.

England, in describing antiseptic dressings which he prepares for use in the Philadel-

phia Hospital, describes as follows his preparation of canton flannel:

Under this term we use in the Philadelphia Hospital a canton flannel rendered absorbent by boiling in a 3 per cent. solution of caustic soda for an hour and a half or two hours, until all the fatty matter in the fibres is decomposed, then washing in several portions of cold water, then macerating the product for ten or fifteen minutes in a 1.5 per cent. solution of hydrochloric acid, whereby any traces of free soda are neutralized, and the fibres of the goods are whitened; and, lastly, followed by several washings in water, wringing out with a machine and drying. This product has been found to be peculiarly serviceable in hospital practice as a cheap, efficient and reliable substitute for all the minor cases for which at present the so-called patent lint is generally demanded; for example, in local applications of lotion of lead-water and laudanum, and as a dressing with various ointments upon chronic sores, ulcers, etc. The proof of its utility may be inferred from the fact that while we used, during 1886, 1500 yards of patent lint, we used also 2500 yards of this absorbent canton flannel. In cost it is almost one-half of that of patent lint.—*American Journal of Pharmacy, Aprit* 1887.

Hydriodate of Hyoscine in Kidney Diseases.

Dr. Tirard, in the *Practitioner*, reports his experience with the following solution:

℞.	Hyoscine hydriodatis,	gr. j.
	Aquæ destillatæ,	♏cc.

Hydriodate of hyoscine is a drug which can be used with perfect safety in cases of kidney disease where morphine is inadmissible. It is a drug which may give rest when other sedatives fail.

If used in two-minim doses subcutaneously, it may give more satisfaction to the patient than to the attendants, since the unconsciousness may be accompanied by angry and combative delirium; should this occur, it will probably be sufficient to diminish the amount employed.

It is very rapid in its action, unconsciousness following in from ten to twenty minutes, and the after-effects are of a soothing character.

Even when delirium is present in a violent form, it is followed by quiet sleep, and the patient being unconscious, is much more refreshed than by a night of short snatches of sleep produced by chloral or bromide, and the result is a marked improvement in both aspect and temper. And lastly, no irritation is produced around the site of injection.

I believe that hydriodate of hyoscine will probably take a firmly-established position as a sedative in cases where morphine cannot be employed.

A Case of Aneurism of the Thoracic Aorta Treated by Galvano-Puncture.

The aneurism was of the first part of the arch of the aorta. The symptoms for a long time were those of insufficiency of the aortic valves, with hypertrophy of the left ventricle. Horribly painful attacks of angina also occurred from time to time, and for these morphia was given hypodermically. After some months the patient was again seen, and a tumor was noticed over the second left costal cartilage, and dysphagia had appeared. The patient being urgent that some operation should be performed which might possibly give him relief, Obelar determined to try galvano-puncture. A Spamer battery of 20 cells was used. The needles were inserted about one inch apart. The current was gradually increased from 2 to 10 cells, and then gradually lowered to 2 again. The séance lasted 10 minutes. In three other séances the number of cells was increased to 20. The patient complained of burning pains in the sac and in the left chest for some hours after each operation. The tumor diminished much in volume, became harder and pulsated less; the dysphagia also was relieved and the general condition improved; the pains, however, continued. After the lapse of a month the tumor again began to enlarge and the pulsations became more evident.

A Device to Secure Fixation of Fragments in Compound Fractures.

Dr. Molloy describes the following method, as seen in Schede's wards at Hamburg:

The treatment of compound fractures presents some novel features. The wound or wounds are laid freely open, irrigated thoroughly with corrosive sublimate solution, 1:1000, all loose splinters of bone removed, fractures reduced, and fixation of the fragments secured by means of a little device of Dr. Hansmann, the first assistant surgeon. It consists of a small metal plate about half an inch wide and as long as is necessary, perforated with holes at short distances. It is laid upon the periosteum, and a screw inserted through one of the holes into the bone on each side of the point of fracture. Two of these little splints are usually em-

ployed in a fracture of a large bone, after which the immobility of the limb is secured in the usual way by splints; the wound being left open and treated antiseptically. The metal plate has the advantage over bone sutures in being much more easy and simple in its application as well as removal, and it secures and maintains the approximation and fixation of the fragments just as firmly.—*Lancet-Clinic*, April 16, 1887.

Olfactory Acuteness.

Nicholls and Bailey (*Medical Press*) have recently published the results of experiments upon the relative acuteness of the sense of smell in individuals. A series of solutions of oil of cloves, nitrite of amyl, extract of garlic, bromine, and prussic acid, were prepared by successive dilutions with water until the limit of perception was reached, and then the solutions were placed indiscriminately and submitted to a number of persons of both sexes to classify them properly by the sense of smell. The results showed that on the average the sense of smell was much more delicate in the males tested than in the females; but the degrees of keenness ranged widely as between individuals. Thus three male observers were able to detect one part of prussic acid in 2,000,000 parts of water, though its presence was not revealed by a chemical test; but others, of both sexes, could not detect prussic acid in solutions of almost overpowering strength. The following figures give the average limit of delicacy of perception: Cloves—Males, 1 in 88,128; females, 1 in 50,667. Nitrite of amyl—Males, 1 in 783,870; females, 1 in 311,330. Extract of garlic—Males, 1 in 57,927; females, 1 in 43,900. Bromine—Males, 1 in 49,254; females, 1 in 16,244. Prussic acid—Males, 1 in 112,000; females, 1 in 18,000.

Stricture of the Female Urethra.

In a paper read before the Obstetrical Society Dr. Herman stated that he had measured the female urethra in fifty-five cases where no urinary trouble was complained of. He found that in the majority No. 17 catheter would pass, and in all but two, No. 14. He related six cases of stricture under his own care, and had collected and arranged in tabular form twenty-three others, which were all he had been able to find reported. The chief cause of urethral stricture in young and middle-aged persons of both sexes was gonorrhœa. In both sexes, also, it might be caused by injury—such cases being proportionately commoner in women on account of child-bearing—or by the cicatrization of chancres. Stricture was also sometimes due to growths of so-called lupus of the vulva, and, in old women, to general fibrous thickening and induration of the urethra, without any history of gonorrhœa or other discernible local cause. As regards treatment, Dr. Herman had found rapid dilatation so simple and successful that he preferred it to any other method.

Sawdust as a Material for Surgical Dressings.

Escher, of Trieste, reports his results with the use of sawdust as a surgical dressing during a year and a half. The material was prepared with corrosive sublimate after Morosoni's method, and was very cheap and efficient. It was found that it could not be made to lie evenly in bags without forming lumps which were painful to the patients. A loose lint called "wood-wool," made from macerated wood fibres, was accordingly incorporated with the sawdust, and furnished a good dressing. In many cases the sawdust was mixed with alcohol and liquid pitch, and gauze was impregnated with the mixture. The sawdust was also enclosed in small sacks made of gauze, which could be conveniently placed over wounds. The results were as good as those obtained with iodoform. The cost was less than that of iodoform, and the sacks were comfortable cushions for the patient, and absorbed discharges very readily. —*Therapeutische Monatshefte, No.* 1.

Formulæ for Lanolin Salves.

The manufacturers of Dr. Liebreich's lanolin salves have published a list of formulæ for their preparation. The following are some of them: 1. Unguentum belladonnæ: Extr. belladonnæ 5.0, lanolini 45.0. Unguentum potassii iodidi: Potassii iodidi 20.0, aqua 10.0, adipis suilli 20.0, lanolin 150.0. 3. Unguentum carbolic.: Acid. carbolic. 5.0, adipis 5.0, lanolini 90.0. 4. Unguentum acid. pyrogallic.: Acid. pyrogallic. 10.0, adipis 10.0, lanolini 80.0. 5. Unguentum acid. salicylici: Acid. salicyl. 10.0, adipis 20.0, lanolini 70.0. 6. Unguentum hydrarg.: Hydrargyri 50.0, lanolini 12.5, ung. hydrarg. 2.5. 7. Unguentum iodoformi: Iodoformi 10.0, adipis 10.0, lanolini 80.0. 8. Unguentum chrysarobini: Chrysarobini 10.0 to 25.0, adipis 10.0, lanolini 80.0. 9. Unguentum picis liquid.: Picis liquid. 20.0, lanolini 80.0. 10. Unguentum ichthyoli: Ichthyoli 10.0, lanolini 90.0. The proportions given are parts by weight.

Strangulation of the Penis in the Head of a Hammer.

In the Polish bi-weekly *Wiadomosis Lekarskie*, No. viii., 1887, p. 243, Dr. Drobner, of Lvov, reports the curious case of a strong and healthy lad of 19, who came to the hospital with his penis tightly fixed in the head of a hammer. The iron weighed 1½ kilogrammes, and the hole measured 3 centimetres in diameter by 4 centimetres in length. The patient had inserted the organ (no doubt with a view to masturbation) about twenty-six hours before, and had since made many fruitless attempts to withdraw it; for the whole of that time he had been unable to pass water. The end of the penis was greatly swollen, its diameter being thrice that of the hole through which it had been pushed. It was only after making thirty deep incisions into the tumefied portion that the imprisoned organ could be liberated. Three weeks elapsed before the parts were restored to their natural condition.

Albuminuria in Diabetes.

Dr. A. Pollatschek, of Carlsbad, published (*Zeitschr. f. Klin. Med.*, xii., 4) some statistical results of the systematic examination of diabetic urine for albumen, with a view to determine whether the occurrence of the latter varied in proportion with the amount of sugar. He found that out of 1187 specimens containing sugar, in amounts varying from traces to as much as 5 per cent., there occurred more or less albumen in 437. The percentage (37) was almost the same, when reckoned on the cases examined in 1885, as on those of 1886, showing a curious uniformity. By grouping the specimens of urine according to their richness in sugar, he shows that there is no constant relation between the amount of albumen and of sugar—the lowest number of albuminurics (29.1 per cent.) occurring in cases of urine with a minimal quantity of sugar, and the highest (43.8 per cent.) in urine having from 2 to 3 per cent. of sugar.

Syphilitic Albuminuria.

M. Horteloup, after some remarks on three cases of albuminuria in syphilitic persons under his care in the Hôpital du Midi, and reported by Dr. Wickham to the Société de Médecine, gives the conclusions at which he has arrived respecting the relations between albuminuria and syphilis. 1. Syphilis may cause albuminuria during the first few months after contagion. 2. This form of albuminuria is easily curable by antisyphilitic treatment, and leaves no trace behind. 3. Such albuminuria ought to be distinguished from that which occurs during the second or third year of syphilis, and which is a much more serious matter as regards prognosis, for it may be looked on as the starting point of chronic nephritis, though this disease may only be found out long afterwards. 4. A syphilitic person, owing to the depression always caused by syphilis, becomes more susceptible to chill, and thus more predisposed to contract nephritis *a frigore*.

Phenate of Mercury in Syphilis.

Professor Gamberini, of Bologna, accepting the parasitic theory of syphilis, conceived the idea of associating a powerful parasiticide, namely, carbolic acid, with mercury, and from his suggestions MM. Boriani and Dallari easily succeeded in producing a preparation called the phenate of mercury. It is prepared by mixing a solution of phenate of potash with a solution of bichloride of mercury. The yellowish precipitate which forms is washed with distilled water until no trace of free bichloride remains. This new salt is prescribed in pills each containing 2 centigrammes (one-third grain), and made up with balsam of Tolu. Two pills a day are given to begin with, and the daily dose gradually increased to six. If more than this quantity is administered, gastro-enteralgia and stomatitis may be set up. The remedy has been employed successfully by the author.

Contagion in the Febrile Exanthemata.

Dr. D'Heilley insists on the proposition formulated by Dr. Girard, of Marseilles—namely, that contagion takes place at the beginning of, and even prior to, the eruption. He quoted the case of a children's party at which thirty-two children were present. Within ten days, twenty-four out of the thirty-two children had measles. Inquiry elicited the fact that one of the children had had measles the day but one after the party, and was already poorly the day of the party. One of the apparently non-infected children was playing with three others about a fortnight later, though a little out of sorts. The day after this child too had the measles, and the three other children also developed it after the usual delay. It is evident, therefore, that measles at any rate are capable of transmission before the eruption has appeared.

Case of Extra-Uterine Pregnancy.

The patient, 27 years of age, had already given birth to a child. The present pregnancy had gone on all right until between the second and third month. At this epoch she had a good deal of abdominal pain. At term false labor pains occurred, and extra-uterine pregnancy was diagnosed. Her condition, however, was such that it was only eight months later that an operation was decided upon. The incision, four centimetres long, was made above and parallel to Poupart's ligament, and as soon as the integument was cut through the fœtal head was seen. Craniotomy was performed and the fœtus extracted piecemeal, in order not to render it necessary to enlarge the opening further. The cavity was washed out with boracic acid solution, and a pre-existing vaginal fistula was utilized for drainage purposes. Recovery was rapid and complete.

Treatment of Burns.

Mosetig-Moorhof, of Vienna, in a series of recent articles in the *Wiener Med. Presse*, protests against the non-antiseptic treatment of burns so commonly carried out. He urges the iodoform dressing; has never seen intoxication from the drug, but the happiest results. After opening the blisters and cleansing the parts with a mild alkaline solution he applies a thick dressing of gauze prepared with iodoform dissolved in ether. Over the gauze he places a piece of gutta percha tissue, and over this a liberal layer of cotton. The wound secretions are absorbed by the cotton, which is readily changed, while the iodoform gauze remains upon the wound for, if needed, fourteen days. He anoints the face with 5 per cent. iodoform vaseline, and covers it with a mask of gutta-percha tissue.

Valerianate of Quinine.

Dr. D. Manuel Delfin reports in the *Cronica Medico Quirurgica*, of Habana, the results of the administration of valerianate of quinine in six cases of acute tetanus, founding the indications for its employment upon his belief that the disease is paludal in its origin. Out of six cases four recovered; one died, who was insane, and refused treatment; and the last one who died was a very severe case, who had once before recovered from tetanus under the use of the quinine preparation. In most cases the more usual remedies—bromides, chloral, etc.—had been previously exhibited without effect. The dose of valerianate of quinine employed at first was one gramme. It is not stated whether this was aftewards increased, or at what intervals it was repeated.

Ordinary Precautions in the Care of the Ears.

Hartmann, of Berlin, in a recent work on otology, gives the following advice:

Under ordinary conditions, the healthy ear does not need to be protected from cold; only during extreme cold or stormy or rainy weather ought cotton-wool to be inserted, into children's ears especially. The same precaution must be taken in the case of every ear predisposed to inflammation. All persons whose membranæ are perforated ought to protect their ears with cotton-wool. The entrance of cold fluids into any ear must always be prevented; and so, while bathing or diving, the ear ought to be plugged. Patients with perforations of the membrane should be very careful in this respect, as violent inflammation may be caused by the entrance of cold water.

A Monkey Affected with Yellow Fever.

During the epidemic of yellow fever which prevailed the first year in Caracas, (*Am. Pract. and News*) we had an opportunity to see in the house of one of our sisters a monkey with an undoubted case of yellow fever. The principal symptoms manifested themselves in a manner so marked that there remained not the least doubt that it was a case of yellow fever that we had before us. There was an injection of the eyes, a certain state of stupor, sharp thirst, nausea, elevated temperature, and at last prostration, anuria, and black vomit.

For three days the poor animal remained in this sad condition, each day growing worse, and presenting in succession the symptoms described, until the fourth day, when the case terminated fatally.

A Case of True Hysteria Cured by Hypnotic Suggestion.

The patient, consequent on peri-uterine inflammation, had the right ovary enlarged and painful, and grave symptoms of hysteria, for the treatment of which castration had been proposed. She was brought to the notice of Mr. Bernheim, who, after several séances, obtained a complete cure. M. Gron, whose patient she was, considered that in cases where grave nervous symptoms seemed to point to castration as a remedy, recourse to hypnotism should always be had before resorting to the operation. M. Bernheim

thought that much of the good which followed castration in these cases was due more to the moral than the physical effect of the operation.

The Microbe of Typhoid Fever.

At a recent meeting of the Société des Hôpitaux, M. Chantemesse made an interesting communication concerning the morphological and biological characteristics of the typhoid microbe. The sporulation of this microbe takes place between 19° and 48° C. (67° to 104.4° F.). It develops in water, even if sterilized. At a temperature of 45° C. (113° F.) the cultivations live for several days; they are destroyed by boiling. This microbe retains its vitality in damp ground. Corrosive sublimate (1 : 20,000) and sulphate of quinine (1 : 800) destroy it. Carbolic acid (1 : 400) has no effect on it; hydrochloric acid is also inert; therefore, the acidity of the stomach is not inimical to this microbe.

A Syphilitic Placenta.

M. Debray described at a recent meeting of the Brussels Anatomical and Pathological Society some peculiar appearances presented by the placenta of a woman who said she had had syphilis a year before her confinement, but who certainly had chancres and a specific roseolous rash at the time. The confinement was at term, and the placenta was removed with some difficulty three hours after the child was born. It was hard and abnormally small. Microscopic examination showed the presence of connective tissue fibres and of numerous plastic elements lying between the connective tissue bundles and forming arterio sclerotic rings round the vessels.

Treatment of Hydrocele by Injections of Corrosive Sublimate.

The solution used is one part of the salt in 1,000 of water. The operation is the same as for injecting iodine. The tunica vaginalis is punctured, and from 200 to 250 grammes of the solution are injected, according to the capacity of the pouch. The scrotum is gently manipulated, and half the solution is then allowed to drain away. It acts as an irritant and gives rise to an inflammation which, while not severe enough to cause suppuration, is sufficient to set up adhesion. There is very little pain. No constitutional symptoms have been observed beyond a slight elevation of temperature.

Incomplete Hæmatocolpos.

V. C., aged 16, domestic servant, first menstruated a year ago, since when there has been a constant discharge of blood. She complains of general malaise and pain in walking. On examination, the hymen was found to be intact and completely closing the vagina. Blood was seen to ooze from two little capillary orifices; these evidently were not large enough to permit of the free egress of the menstrual discharge. An incision was made with the scissors, and a quantity of retained blood escaped. On the next day all discharge had ceased, and twenty-two days after the period appeared naturally.

Enemata of Defibrinated Blood.

Cases in which enemata of defibrinated blood have been employed in the treatment of chlorosis and acute anæmia are reported by Dr. Valera in the *Siglo Medico*, and by Dr. Mariani in the *Revista*. Dr. Valera's case was one of extremely severe post-partum hemorrhage, and was combined with the use of the cold douche. Dr. Mariani's cases appear to have been instances of simple anæmia. In each case improvement is stated to have been rapid, and the recovery permanent; but the details as to the mode of administration, or the nature of the blood employed, are not given.

Prescriptions for Amenorrhœa.

Upshur, of Richmond, Va., in "Disorders of Menstruation," gives the following as his favorite formulæ in anæmic amenorrhœa:

℞. Tinct. ferri chlorid., ℥ j.
Liq. chlor. arsenici, ♏ ij.
Strychniæ, gr. j.
M. Sig.—Gtt. xx. t. i. d., after meals in water.

℞. Tinct. ferri chlorid., ℥ ss.
Acid. muriatic. dil., ♏ iij.
Liq. chlor. arsenici, ♏ ij.
Hydrarg. bichloridi, gr. j.
Syr. zingiberis, ℥ ij.
Aquæ, ad. ℥ vj.
M. Sig.—Take a teaspoonful in one-third of a tumbler of water three times a day, after meals.

Inhalations of Defibrinated Blood.

Dr. Escorileada also records in *El Genio Medico Quirurgica* an example of extreme anæmia with anorexia occurring in a female patient, aged 29, in which defibrinated and diluted bullock's blood was given in the form of a spray by inhalation, as recommended by Jubini, the defibrinated blood being in the proportion of 80 per cent, to 20 per cent.

of .75 per cent. salt solution. Other treatment had failed to improve the nutrition, but visible improvement was noted after four inhalations. Cold affusion with sea-water was also employed.

How to Give Castor Oil.

Dr. Field, in a recent book, "Evacuant Medication," gives the following formula as useful in administering castor oil, especially in dysentery and enteritis, when purgation and a healing and tonic influence is required:

℞.	Ol. terebinth.,	gtt. 80.
	Ol. cinnamon,	♏. 5.
	Ol. ricini,	ʒ 5.
	Mucil. acac.,	q. s.
	Syr. simpl.,	q. s.
	Aq. puræ, q. s. ad.	℥ 2.

M. Sig.—Shake thoroughly. One teaspoonful, repeated *p. r. n.*

Ammonium Picro-Nitricum.

May be given, for malarial infection, as follows:

℞.	Ammonii picro-nitrici,	gr. 5 to gr. 23.
	Pulv. rad. liquiritiæ,	
	Succi liquiritiæ, āā	♏ 23.

M. Ft. pil. xxx. in num.

These pills should be prepared with moist excipient, as picric acid forms explosive compounds in the dry state.

An Ointment for Freckles.

Hebra:

℞.	Hydrarg. precipitat. albi.,	gr. 75.
	Bismuth. subnitrat.,	gr. 75.
	Glycerinæ unguent.,	ʒ 5.

M. Ft. unguentum.

Sig.—Apply every 2 or 3 days; it will irritate if used too frequently.

Prescription for a Convenient Quinine Pill.

℞.	Quinine sulph.,	gr. 30.
	Sacch. alb.,	
	Gummi Arab., āā	gr. 15.

M. Ft. pil. xxx. in num.

These pills are very soluble, and make up well.

Chorea Cured by Antipyrin.

Wallner reports a case of a girl aged 16, whose disease had resisted other remedies, who was cured by 15 grains of antipyrin three times daily. The cure was complete in twelve days.—*Therapeutische Monatshefte*, No. 1.

News and Miscellany.

Commencement of the Medical Department of the University of Pennsylvania.

The commencement exercises of the Medical Department of the University were held at the Academy of Music on Monday the 2d inst. at 11 a. m.

After prayer by Rev. Dr. H. J. Morton, the degrees in medicine were conferred by Dr. William Pepper, Provost of the University. The medical graduates were:

NAMES OF THE GRADUATES.

Americus R Allen, George E. Andrews, A. B., William A. Atlee, Jr.

George Fales Baker, B. S. Tilghman, M. Balliet, A. B., Delbert Barney, A. B., Reuben H. Bemish, T. Passmore Berens, Cuthbert F. Bowen, B. A., David P. Bowman, B. E., Edward T. Bradley, Leon Brinkmann, Samuel W. Burns.

George A. Cameron, Paris T. Carlisle Jr., Henry W. Cattell, A. B., Joseph G. Church, J. A. Coleman Clarkson, A. B., J. Vale Cleaver, Cary K. Clewell, R. Percy Crandall, George C. Curtis, D. D. S., Millard F. Cyphers.

James A. Davis, Ph. G., Charles Dingee, John George Doron, A. B., Malcolm Douglas, Jr.

Lambert H. Edgar, Thomas C. Ely, Jr., Ph. B., Alexandro Espinoza.

William W. Farr, Alexander G. Fell, B. S., Charles Fitzpatrick, Jr., William M. Frost, A. B., George B. Fundenberg, Jr., A. M.

John P. Gale, S. A. Mercer Givin, George B. Glover, A. B., Horace S. Grant, Elijah Griffith, Thomas A. Grigg.

Thomas H. Hartswick, Charles A. Hartzell, Joseph Head, D. D. S., John Clement Heisler, Ph. G., Alfred Davis Henkel, Arthur C. Hugenschmidt, D. D. S., Charles D. Hunt, Randall Hutchinson, A. B.

John E. Jennings, Theodore M. Johnson, Ph. G., Kent C. Jones, Le Roy H. Jones.

Louis J. C. Kimmell, Pearce Kintzing, B. S., Ellwood R. Kirby, Ira D. Knotts.

Alfonso Lacayo, A. B., Frederick Lambach, Jr., Joseph Leidy, Jr., A. B., Jere W. Lord, A. B.

Jose J. Macias, Ph. B., Jacob F. Marchand, A. M., Bernard G. Maercklein, D. D. S., Charles B. Martin, Peter J. J. Martin, James M. Maurer, A. B., Leonidas L. Mial, A. B., Peter F. Moylan, John B. McAlister, A. B., Charles A. McCauley, John W. McCauley, A. B., Robert McCreight, Ph. G., John J. McDonald, M. D.

S. Pusey Nickle, Richard C. Norris, A. B., Frederick W. Prentice, M. D., William L. Pyle.

Benjamin B. Reath, Jr., A. B., Jeremiah V. Reeder, George F. Roessler, Ph. G., Francis Rudderow, A. B.

Sebastian Salinas, B. S., Joseph R. Smith, Theodore Sprissler, Ph. G., B. Franklin Stahl, Ph. G., James Stein.

Frank W. Talley, William B. Taylor, A. B., William C. Townes. Ph. B., John Harry Trout, Ph. G., Thomas Turnbull, Jr., Richard Raymond Tybout.

William J. Walker, George D. Weston, B. S., Sven Windrufva, M. F. C., John A. Witherspoon, Stephen Carroll Wood, A. B.

DR. GOODELL'S ADDRESS.

Dr. William Goodell, the professor of clinical gynæcology, then delivered the valedictory address. After special reference to his thirty-three years, experience he said:

"The influence of an honored physician in this community is always great. He and the clergyman and the lawyer are often the only educated men in their village. As the title which you have just now received at the Provost's hand, as the word 'doctor' means, you are to be teachers as well as healers—the educators and refiners of those among whom you cast your lot. One man of you—and by 'man' I do not mean one who hangs about tavern porches or lounges about drug stores—one man of you, I say, can give tone and character not only to a township but to a county. However popular you may be with your fellow townsmen, do not accept all the honors they may thrust upon you. To be at the same time mayor of your borough, chairman of your school board, and an active politician, is a great mistake. Remember that the profession you have chosen is a mistress too imperial and too imperious to brook a rival." Dr. Goodell specially warned his hearers against intemperance, and impressed upon them their duty in elevating the profession and maintaining its dignity.

Prizes were awarded as follows:

The *Medical News* prize, $100, divided between Dr. Arthur C. Hugenschmidt, Paris, for his thesis, "Experimental Studies upon Man," and Peter J. Martin, of Pennsylvania, for his thesis on "Physiological Action of Antipyretics."

The award of "distinguished merit" was given to F. Passmore Berens, for his thesis on "Amylolytic Ferment of Human Milk."

"Honorable mention" was awarded to William C. Townes, of Mississippi, for his thesis, "A Continual Study of the Tumors Removed at the Surgical Clinics of the University Hospital, January to June, 1886," to Sven Windrufva, of Sweden, and Randall Hutchinson, of New Jersey.

The following prizes were awarded by Dr. J. William White, Demonstrator of Surgery, for proficiency in operating and bandaging: A copy of Agnew's "Surgery," to Joseph Head, of Pennsylvania; a surgical pocket case to Joseph Leidy, jr., of Pennsylvania. A third prize for the same work, offered by J. B. Lippincott Company, a copy of Agnew's "Surgery," was awarded to Sven Windrufva, of Sweden. The operating and bandaging of the following graduates received honorable mention: Richard J. Norris, of District of Columbia; Randall Hutchinson, of New Jersey; Leonidas Mial, of North Carolina; W. J. Walker, of Pennsylvania, and Peter J. Martin, of Pennsylvania.

Dr. N. Archer Randolph, Professor of Hygiene, awarded to Samuel M. Wilson, Pennsylvania, a Zentmayer's histological microscope for the best examination on hygiene. J. L. Hatch, of the auxiliary department of medicine, received honorable mention of his work on hygiene.

William M. Abach, of Pennsylvania, received a copy of Agnew's "Surgery," for proficiency in bandaging by first year students.

In this same line of work honorable mention was accorded Joseph P. Tunis, of Pennsylvania; Albert S. W. Johnson, of Nassau, W. I.; W. C. Posey, of Pennsylvania; Alfred Stengel, of Pennsylvania, and Clarence A. Butler, of Pennsylvania.

H. M. Keller, of Stroudsburg, was announced as one of the graduates, but his diploma was withheld until next year, because he was not of age.

The exercises closed with the benediction by Dr. Morton.

THE ALUMNI DINNER.

In the chapel of the University, on the evening of the same day, the alumni association of the Medical Department held its seventeenth anniversary banquet. At the head of the table was Dr. R. A. Cleeman, and around it were gathered over 150 graduates.

The first toast was the "Faculty," and was responded to by Dr. Horatio Wood. He paid tributes to many members of the faculty, and especially referred to Professors Jackson, Hodge and Leidy.

"The Relations of the Profession to the Community," was responded to by Talcott Williams.

"The Medical Press" was responded to by Dr. N. Archer Randolph, "The Class of '77" by Dr. Formad, and "Our Sister College" by Dr. Parvin, of the Jefferson College.

The committee having the arrangements in charge consisted of Dr. Cleeman, Dr. S. D. Risley, Dr. H. A. Hare, Dr. William Pepper, Dr. James Tyson, Dr. H. R. Wharton, Dr. William Barton Hopkins, and Dr. T. R. Neilson.

Among those present were: Dr. Huidekoper, Professor Wormley, A. Sydney Roberts, L. Clark Davis, Professor Agnew, Dr. I. Massey, of West Chester; Dr. Hartswick, of Clearfield.

Sudden Death.

"I fear you are too late," said the husband, as he hurried me to the apartment where his wife, from sudden failure of the heart's action, was lying insensible, and as the nurse informed me, "dying." It was impossible to administer by the mouth a restorative, so without delay I injected hypodermically twenty drops of ether, sp. gr. 0.720, and, as the improvement was not as quick as I desired, forthwith twenty drops more. To the complete astonishment and great delight of the friends, consciousness and strength rapidly returned.

The sudden deaths which have so lately thrilled the public mind, more especially the death of Lord Iddesleigh, in London, and Mr. Christopher Bushell here, have influenced me to send you the above record, not as the proclamation of a new discovery, but as a suggestion—a suggestion in connection with the alarming newspaper reports which usually run somewhat thus: "Mr. —— suddenly became ill, when, sinking, he was supported by his friend. Dr. ——, who happened to be present, was most assiduous in his attention, but at last pronounced life extinct." Should it not be impressed on the public that the easiest mode in which respiration can be carried on is when the body is extended at full length—not lying on the back, but with the inclination towards the prone position? Nature throws down to assist the encumbered circulation; the officious kindness of indiscretion and ignorance supports the fainting sufferer. Again, would it not be well in these times of frequent sudden deaths from weakened hearts that each medical man should have in his possession, ready for immediate use, his hypodermic syringe case, with its little bottle filled with ether? Would it not be well, too, that the possessor of a weak heart, or, better still, the friend who accompanies him, should also have the ether and syringe ready for instant employment? Ladies with neuralgia practice hypodermic injections of morphia by the advice and under the direction of physicians. This I would condemn. But the friend of a valuable life, the tenure of whose leasehold is uncertain through the possession of a weakened, or flabby, or a fatty heart, might well be instructed in the use of the subcutaneous injection of ether. More than one example might be adduced to show that the immediate stimulant might rouse the flagging pulse-throb; and then, instead of the announcement that "life was extinct," one might read that after the injection the the appalling symptoms quickly passed away, and what appeared to be approaching death gave place to the renewed energy of life, with all its usefulness.—*Lancet April* 23, 1887.

The Association of Genito-urinary Surgeons,

Which has lately been organized with Dr. Edward L. Keyes, of New York, as temporary chairman, and Dr. Robert W. Taylor, of New York, as temporary secretary, will hold its first annual meeting at the Laurel House, Lakewood, N. J., on Tuesday and Wednesday, the 17th and 18th of May. In addition to an address of welcome, by the temporary chairman, the programme includes the following named papers: "The Connection between Masturbation and Stricture of the Urethra," by Dr. S. W. Gross, of Philadelphia; "On Chancroid," by Dr. F. B. Greenough, of Boston; "On Horny Growth of the Penis, with exhibition of a Remarkable Case," by Dr. J. H. Brinton, of Philadelphia; "Supra-pubic Cystotomy for Vesical Tumor and Large Calculus, with Comments upon Suture and a Suggestion for Drainage," by Dr. E. L. Keyes, of New York; "Case of Hysterectomy for the Relief of Pyelitis from Obstruction," by Dr. A. T. Cabot, of Boston; "On the Choice of Operation for the Removal of Vesical Calculus in Cases complicated by Prostatic Obstruction," by Dr. J. P. Bryson, of St. Louis; "Idiosyncrasy as affecting the Specific Treatment of Syphilis," by Dr. P. A. Morrow, of New York; "Observations on the Use of Oil of Wintergreen in the Treatment of Gonorrhœal Rheumatism," by Dr. R. W. Taylor, of New York; "Some Cases of Pyelitis in which Frequent and Painful Micturition was the Chief Symptom," by Dr. George Chismore, of San Francisco; "On Temporary Over-strain of the Bladder producing Chronic

Retention of Urine," by Dr. F. N. Otis, of New York; "Early Syphilitic Epididymitis," by Dr. J. N. Hyde, of Chicago; "Prostatotomy for Obstruction—Two Cases," by Dr. A. T. Cabot, of Boston; "A Plea for the More General Use of Nitrate of Silver in the Deep Urethra, with an Improved Instrument for its Application," by Dr. E. L. Keyes, of New York; "A Rare Form of Septicæmia following Operation for Urethral Stricture—*Septicémie foudroyante gazeuse*," and "Exhibition of Sections of Tubercular Testes with Bacilli, and of the Coëxistent Bacilli in the Sputum," by Dr. R. W. Taylor, of New York.

Terebene and the London Apothecaries.

A correspondent of the *British and Colonial Druggist* says: "I am, as you are aware, 'connected with the trade'—the last word should perhaps have been 'profession,' but that will not affect the value of my narrative. Staying in London for a few days was a friend of mine, and as one evening this week we were investigating the mysteries of the metropolis it became apparent that his interest was beginning to flag. With the instinct of a pharmacist who may one day have to prescribe in order to pay his rent and taxes, I soon detected reflections of physical pain in the countenance of my companion, Ably following up the symptoms, I arrived at the truth—stomachic inflation. Good! Terebene indicated. Get some. To the nearest chemist we went. He was busy. Happy man! Five real customers in his establishment at one time. Not revealing 'my connection with the trade,' I modestly preferred a request for five drops of terebene in a little water. 'Terebene?' quoth the professional gentleman behind the counter. I assented. 'Terebene?' he repeated; 'what for?' 'Flatulence.' He smiled broadly. 'Terebene!' he continued. 'I've heard of "Terebene Soap."' Again smiling in a manner which plainly meant 'I am a man of superior knowledge, but I'll give you another chance,' he inquired, 'Are you sure it's *terebene?*' I was. Then came his thunderbolt. 'Why, terebene's a kind of turpentine. You don't want to take that internally.' I was crushed, and we retired.

"We had an almost similar experience in the next pharmacy we went to, and I was there told I must be mistaken about the name. I must mean 'peppermint.'

"Three more establishments were visited, but none of them had terebene in stock. All these five pharmacies were in the W. C. district, and in selecting these to call at I avoided, after my interview with the 'Terebene Soap Man,' several shops of inferior size as being unlikely places to get what I wanted."

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS.

Medical Department U. S. Army, April 26 to May, 2, 1887:

Major John S. Billings, surgeon, granted leave of absence for ten days, to take effect May 3, 1887. S. O., 98, A. G. O., April 28, 1887.

First Lieutenant Chas. E. Woodruff, assistant surgeon—(Recently appointed), ordered for duty at Ft. Wayne, Mich. S. O., 96, A. G. O., April 26, 1887.

Medical Corps of the Navy, for the week ending April 30, 1887:

Assistant Surgeon L. W. Atlee, ordered to the Receiving-ship Vermont.

Past Assistant Surgeon Clement Biddle, detached from the Naval Academy, and to Marine Rendezvous, Philadelphia, Pa.

Past Assistant Surgeon Richard Ashbridge, ordered to the Naval Academy.

Medical Inspector A. Hudson, ordered to the United States Steamship, Trenton.

Past Assistant Surgeon C. T. Hibbett, ordered to the United States Steamship, Trenton.

Assistant Surgeon Corbin J. Decker, detached from the Receiving-ship, St. Louis, and to the United States Steamship, Trenton.

U. S. Marine Hospital, for the three weeks ended April 30, 1887:

Goldsborough, C. B., surgeon. Leave of absence extended thirty days on account of sickness. April 20, 1887.

Devan, S. C., past assistant surgeon. Granted leave of absence for thirty days, to take effect when relieved. April 12, 1887.

Bratton, W. D., assistant surgeon. To proceed to Port Townsend, W. T., and assume temporary charge of the service. April 21, 1887.

A Chance for Anti-Tobacconists.

The Société contre l'Abus du Tabac offers the following prizes: 1. A prize of 500 francs ($100), with a gold medal worth 100 francs ($20), is offered by Dr. Depierris to medical students belonging to any school in France for the best treatise on "Nicotic Cachexia: its Symptoms, Progress, and Effects; demonstrated by at least eight clinical observations, made either in the hospitals or in civil or

military practice." It may be written in the form of a thesis, but this is not obligatory. The prizes are open to all students, no matter what their standing. Other medals will be awarded to the authors of any treatise of exceptional scientific value. 2. A prize of 900 francs ($180) (*Prix des Gens de Lettres*), with a gold medal worth 100 francs, is offered by Dr. Depierris for the best treatise on "The Effects of Tobacco on the Health of Men of Letters: its Influence on Future French Literature." 3. A prize of books worth 200 francs ($40) (*Prix de Médecine*) is offered for the four best detailed reports of cases (including etiology, symptoms, termination, etc.) of affections due exclusively to the abuse of tobacco. A medal will also be awarded with this prize. The essays may be written in French, English, German, Italian, or Spanish, and they must be sent in before December 31st, 1887. Full particulars as to the conditions of the competition will be forwarded free, on application to the President de la Société contre l'Abus du Tabac, 38 Rue Jacob, Paris.

The Pennsylvania Hospital.

The 136th annual meeting of the contributors to the Pennsylvania Hospital was held on Monday, May 2.

From the report of the Board of Managers it appears that the total number of cases treated at the hospital during the past year was 13,401, the expenses for the maintenance of the sick, $64,158.77. The report mentions the introduction of a new system of hospital management, which supplies closer bedside administration, and separates from the latter the general housekeeping duties.

The antiseptic treatment, which has recently been thoroughly established at the hospital, was dwelt upon at some length.

On Wednesday, the 4th instant, Dr. John Ashhurst was elected as one of the surgeons of this institution, *vice* Dr. Richard J. Levis, resigned. His acceptance has not yet been received.

The Expense of Quackery.

There are in San Francisco, says the *Pacific Record*, one hundred and twenty-five illegal practitioners—*i. e.*, those whose ignorance is so appalling that they could not obtain a license from any of the examining boards. In the State there are over five hundred of this class. Some of them spend large sums monthly for advertising. We know of one whose advertising bills are two thousand dollars a month. Two practitioners on Kearney Street spend each one thousand dollars a month, and one on Market, two thousand. This last declares that his receipts from his practice and sale of nostrums will average *one hundred dollars a day*. The amount (average) filched from their dupes by each of these swindlers cannot be less than two hundred dollars a month, or one hundred thousand dollars in the aggregate. This is $1,200,000 a year.

Addresses in the General Sessions of the International Medical Congress.

Many of the medical journals in this and other countries have announced the fact that Professor F. Semmola, of Naples, Italy, is to give a general address on "Bacteriology and its Clinical Therapeutics," to the Congress in general session; and we will add that general addresses are also promised by Dr. Neudorfer, of Vienna, Austria, "On the Military Medicine of the Present and of the Near Future;" Dr. Esmarch, of Kiel, Germany, "On Bloodless Operations in Surgery;" Dr. Lutaud, of Paris, France, "On the Influence of the Discoveries of American Surgeons on the Development of Gynecology in Europe," and Dr. Austin Flint, of New York, N. Y., on "Fever, its Cause, Mechanism and Rational Treatment"—all topics of interest to the whole profession.

The Congress.

The *New England Med. Monthly* says: As time slowly passes, the Executive Committee of the Ninth International Medical Congress keep pace with its arrangements for the successful conduct of this important meeting. Advices constantly received by them from abroad indicate without a doubt that there will be large and influential delegations from France, Germany, England, Ireland, Austria, Denmark, and other countries. That these delegations will be representative, is indicated by the fact that the gentlemen offering to read papers before the various sections are men of world-wide reputation. The local committee of arrangements have been actively at work, and we are warranted in saying that the social part of the meeting will be all that the most fastidious could desire.

Charcot.

George Augustus Sala says: Dr. Charcot is surely one of the most ingenious of the

medical mankind. He is a specialist in hysteria and hypnotic cases, and I read that, having satisfied himself as to the practicability of transferring paralysis, nervous contractions and cataleptic symptoms from one patient to another, he is now about to extend his experiments to hysterical dumbness. A female patient affected in this manner was placed back to back with a woman who had been for a long time cataleptic. By means of the magnet the dumbness was transferred from one patient to the other with the same regularity as marked the experiments in paralysis. By continuing these tests, Dr. Charcot hopes to be able to completely restore speech to tongue-tied patients.

Longevity of the "Friends."

The "Friends" are noted for their simple modes of life and their close observance of all the laws of hygiene and of health, and their vital statistics speak louder than a voice of flame for closer attention to public health. Of the 229 "Friends" who died last year in Great Britain and Ireland, only 22 were under five years of age; between five and ten years were five deaths; between ten and twenty years, 9; from twenty to thirty years the deaths numbered 18; from 30 to 40 years, 16; from 40 to 50 years, 22; from 50 to 60 years, 23; from 60 to 70 years, 51; from 70 to 80 years, 74; from 80 to 90 years, 69; from 90 to 100 years, 10. The low infantile mortality and the large percentage of deaths at great ages are remarkable even for the Society of Friends.

Hygienic Congress.

On May 8, the Federation of the Italian Hygienic Societies will hold its first Congress in Florence. The sittings will last till the 10th, and among the proceedings will be a discussion on the new code of public hygiene submitted to the Italian Senate by the Prime Minister, Depretis, and a paper by the Senator, Professor Pacchiotti, of Turin, on the "Vaccinazione Anti-rabica" of Pasteur. The great *feste*, of which during the first three weeks of May the Tuscan capital will be the seat, form an attraction of which the promoters of the Congress will avail themselves for enhancing the success of their inaugural meeting.

Louisiana State Medical Society.

The ninth annual meeting of this Society was held in Alexander, La., April 11, 12, 13, 1887. Valuable papers and reports were presented, and several topics of special interest to the profession of that State were discussed. The following officers were elected for the ensuing year: President, Dr. Joseph Jones, New Orleans, La.; Vice-Presidents, Drs. F. H. Parham, of New Orleans, H. D. Bruns, of New Orleans, Thomas Hebert, of New Iberia, F. M. Thornhill, of Arcadia, I. J. Newton, of Bastrop, and T. T. Tarleton, of St. Landry; Secretary, Dr. P. B. McCutcheon, of New Orleans. The next annual meeting is to be held at Monroe, La., on the third Wednesday in April, 1888.

Tennessee State Medical Society.

At the annual meeting of this society, held in Nashville, April 12 and 13, 1887, the following officers were elected for the ensuing year: President, Dr. P. D. Sim, of Chattanooga; first Vice-President, Dr. Happel, of Trenton; second Vice-President, Dr. R. Douglas, of Nashville; third Vice-President, Dr. J. M. Masters, of Knoxville; Secretary, Dr. Ambrose Morrison, and Treasurer, R. Cheatham.

The society contribnted $250 for the Treasury of the International Medical Congress to be held in Washington, D. C. Its next annual meeting, in 1888, will be held at Knoxville.

Medical Association of the District of Columbia.

At the regular meeting of this Association, held April 5, 1887, the following officers were elected for the ensuing year: President, Dr. J. W. Buckley; Vice-Presidents, Drs. J. W. Bayne, and W. O. Baldwin; Secretary, Dr. Lachlan Tyler; and Treasurer, Dr. S. S. Adams.

Chicago Medical Society.

At the annual meeting of this Society, held at the Grand Pacific Hotel, April 4, 1887, the following officers were elected for the year: President, Dr. Wm. T. Belfield; Vice-Presidents, Dr. J. H. Etheridge, and Dr. A. E. Hoadley; Secretary, Dr. Frank Billings; and Treasurer, Dr. H. N. Moyer.

American Dentists in Berlin.

Under date of March 30th, the Polizei-Präsident advertises in the "Deutsche Medizinal-Zeitung" a decree ordering all persons not possessed of an approved medical quali-

fication to discontinue within three months the use of the title "American dentist" on signs, cards, etc. The reason given is, that the title so resembles that of a physician that it may give the impression that the bearer of it is "eine im Inlande approbirte und geprüfte Medicinal Person."

Education of Women in Germany.

Of late the Prussian Minister of Education has had several applications made to him to admit women as students at the universities. His reply is, that women are not to be admitted as regular students at any Prussian university, nor at any of the medical schools.

The University of Berlin.

The *Lancet* states that Dr. Olshausen, of Halle, has accepted an invitation to fill the late Professor Schroeder's chair of obstetrics, and will begin his lectures on the 1st of May.

Items.

—Dr. Davis (*Therap. Gaz.*) states that tea-drinking acts in the direction of producing sterility in females.

—Dr. Lewis Sayre's Clinical Lectures on Orthopædic Surgery have been translated into French by Dr. Henri Thorens.

—The Ontario Medical Association will hold its seventh annual meeting in Toronto, on Wednesday and Thursday, June 8th and 9th.

—The term of service of Surgeon-General Gunnell, as Chief of the Bureau of Medicine and Surgery of the Navy, expires in March, 1888.

—According to *L'Union Médicale*, M. Lannelongue has been elected to succeed the late M. Béclard as a member of the Academic Council.

—The American Climatological Association will hold its fourth annual meeting in Baltimore, on Tuesday and Wednesday, May 31st and June 1st.

—The State Medical Society of Arkansas will hold its twelfth annual meeting in Little Rock, on Wednesday, Thursday, and Friday, June 1st, 2d, and 3d.

—The Trustees of the University of Pennsylvania have just received the preliminary report of the Seybert Commission, in regard to its investigation on the subject of spiritualism. It was ordered to be published.

—It is reported (*L'Union Médicale*) that a case of opium narcosis was relieved by nitrite of amyl after belladonna had failed, and the patient was almost dying.

—A writer in an exchange says that in experiences in Colorado and Utah he never saw an Indian with a cold. He concludes that it is our hot rooms that give us colds.

—Retention of urine may frequently be relieved by a sudden dash of cold water upon the supra-pubic region, or will prove amenable to the application of ice to the perineum, or its introduction into the rectum.

—A Parisian doctor prescribed for a lady who had objections against growing stout: "Take exercise, my dear lady. Consider the trees of the field; they never take exercise, and as a consequence they go on growing bigger and bigger every year."

—Inebriety cannot be prevented by throwing the responsibility on the inebriate, and punishing him for this as if for a crime. He is a sick man, and must be taken out of his surroundings and fully quarantined until he can recover.—*Quarterly Jour. Inebriety.*

—For the relief of the violent pains that in some women precede the menstrual flow, Dr. Meniére, of Paris, gives a warm water enema, containing thirty grains of chloral, and thirty grains of bromide of potassium. For young women one-half of the above quantities should be prescribed.

OBITUARY NOTICES.

Moritz Schuppert, M. D.

New Orleans, May 3.—Dr. Moritz Schuppert, the eminent surgeon, died last evening, aged sixty-nine years.

Alexander Leslie, M. D.

Evansville, Ind., May 3.—Dr. Alexander Leslie, of Petersburg, Pike county, Ind., died on Sunday. He was one of the oldest practitioners in this section, seventy-three years of age, and having practiced fifty-four years.

John M. Dallam, M. D.

The death of Dr. John M. Dallam, in Tioga on Monday last, is announced. He was born near Baltimore sixty-one years ago. His ancestors were among the earliest settlers in Maryland, and prominently identified with the American Revolution. The Doctor studied medicine in the University of Pennsylvania, and his professional life has been spent in this city, and mainly in the community where he died.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

GREEN SPRING SANITARIUM,
AND
WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten aces. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and massage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

BELLEVUE HOSPITAL MEDICAL COLLEGE,
CITY OF NEW YORK.

SESSIONS OF 1887-88.

The REGULAR SESSION begins on Wednesday, September 21, 1887, and ends about the middle of March, 1888. During this Session, in addition to the regular didactic lectures, two or three hours are daily allotted to clinical instruction. Attendance upon at least two regular courses of lectures is required for graduation.

The SPRING SESSION consists of recitations, clinical lectures and exercises, and didactic lectures on special subjects. This Session begins about the middle of March and continues until the middle of June. During this Session, daily recitations in all the departments are held by a corps of Examiners appointed by the Faculty.

The CARNEGIE LABORATORY is open during the collegiate year, for instruction in microscopical examinations of urine, practical demonstrations in medical and surgical pathology, and lessons in normal histology and pathology, including bacteriology.

For the annual Circular and Catalogue, giving requirements for graduation and other information, address Prof. AUSTIN FLINT, Secretary, Bellevue Hospital Medical College, foot of East 26th Street, New York City.

Lecture.

AN INTRODUCTORY LECTURE ON INJURIES AND DISEASES OF THE URETHRA.

BY G. FRANK LYDSTON, M. D.,

Lecturer on the Surgical Diseases of the Genito-Urinary System and Venereal Diseases in the College of Physicians and Surgeons, Chicago, Ill.

Reported by William Whitford.

Gentlemen: I shall direct your attention this morning to the consideration of the injuries and diseases of various kinds that affect the male urethra, and before considering these morbid conditions, I would like to say something about the general management of cases of urethral or genito-urinary diseases, whether they be acute or chronic, inflammatory or neurotic, or simply irritative in character. The first consideration in the treatment of affections of the genito-urinary tract is the condition of the urine. Normal urine is more or less acid, but the exact degree of acidity, which is physiological, would be difficult to determine. It varies in different individuals, varies with the diet, the amount of physical exercise taken, and with the condition of the genito-urinary organs. The acid urine is always more or less irritating to the mucous membrane in all acute or inflammatory affections of the genito-urinary apparatus, and it is the correction of this acidity that chiefly demands our attention. In every case of genito-urinary disease in which there exists irritation or inflammation, the first indication is to neutralize the normal acidity of the urine; or better, to make it slightly alkaline if possible, by internal medication, regulation of the diet, and attention to vicarious elimination of the products of retrograde metamorphosis. Neutral or faintly alkaline urine is much less irritating to the inflamed mucous membrane than the normal secretion. A very peculiar fact in connection with the consideration of the irritating properties of the urine in inflammatory troubles of the genito-urinary tract is, that even in those chronic cases of cystitis in which the voided urine is strongly ammoniacal, alkaline remedies are beneficial. The acid urine, as it comes down from the kidneys, irritates the bladder; the excessive secretion of mucus thereby induced produces fermentation of the urine, and this fermentation results in ammoniacal decomposition. Thus the primary source of the irritation is the acid urine.

It produces irritation of the mucous membrane, and thereby enhances the existing inflammation and excessive secretion, this being followed by urinary decomposition. The primal indication therefore is to give proper remedies to lessen acidity, and thus allay the irritation and inflammation. There are various medicinal agents that act upon the urine and render it alkaline, the best of these being the citrate and acetate of potassium. These combinations of alkaline salts with the vegetable acids are especially useful for producing alkalinity of the urine, in the surgical diseases of the genito-urinary organs, or, at least, neutralizing its acidity, and may be given in doses of from ten to twenty grains three to five times daily.

Another important consideration in reducing the acidity of the urine is attention to diet. I presume that no patient can take a non-nitrogenous diet for any length of time without causing more or less alkalinity of the

urine. A typical diet, although not entirely non-nitrogenous, is bread and milk; milk is mildly alkaline in its reaction, and when taken in large quantities, providing the patient takes no meat, will produce a neutral or faintly alkaline condition of the urine. My own practice, in all inflammatory troubles of the genito-urinary tract, is to confine the patient to a strictly bread and milk diet; this being my first prescription in cases of gonorrhœa, cystitis, prostatitis, etc. I have met with many cases of acute gonorrhœa in the dispensary that I have treated exclusively by a bread and milk diet, and the administration of the acetate of potassium, and with no other remedies than these, the inflammatory symptoms have subsided quite promptly. It is my custom to give astringents or balsams in appropriate cases, after the acute symptoms have begun to subside, but I would not advise treatment which is in the least apt to prove stimulating, for the first week or two after the beginning of a gonorrhœa, and I think that you will find that if you put all your patients with acute inflammations of the bladder or urethra, upon a bread and milk diet with simple diluent remedies, they will almost invariably do well. I have even seen chronic cases recover completely after the suspension of all astringent and balsamic preparations by the patient subsisting, for a few weeks, entirely upon bread and milk.

Another important point is, that we must pay strict attention to the skin and bowels. If these emunctories do not act properly, the kidneys must necessarily be called upon to act vicariously, thus rendering the urine more irritating. One of the primary indications therefore, is to increase the secretion of the skin, and thus remove the waste material which would otherwise render the urine extremely acid. This is especially necessary in patients of a rheumatic or gouty diathesis, who eat and drink to excess. The skin and bowels may be stimulated by very simple remedies. The Turkish bath is useful in increasing the action of the skin; while such simple laxatives as the compound licorice powder or any of the saline mineral waters, are sufficiently powerful to keep the bowels active.

Another indication of the treatment of inflammatory troubles of the genito-urinary organs is the maintainance of perfect rest, but with the majority of patients suffering from such diseases this is a difficult thing to accomplish, as patients do not, or will not, understand the importance of it. A patient will come into your office with a clap and expect to be cured while he is going about attending to his business and social duties; and in deference to professional custom, and a desire to retain the patient, you will usually be compelled to treat him as best you may, while he is on his feet and actively exercising, when, as a matter of fact, he ought to be taking rest, or even put to bed for eight or ten days. I do not say that it is always absolutely necessary or practicable for him to lie in bed, but such a course is certainly indicated in the majority of cases, and you can always instruct your patient to keep just as quiet as possible, and to avoid walking about a great deal, or taking undue muscular exercise during the time he has the acute inflammation. In cases of inflammation of the prostate or bladder, you will very often be compelled to place your patient in bed for a greater or less length of time. I have had cases of acute and chronic prostatitis come under my notice that have been treated in every conceivable way without benefit, and which have only been cured after two or three months in bed. A little while ago I was consulted by a physician who was suffering from a prostatitis of five or six months' standing, that had been treated by nearly all known methods at the hands of a number of eminent practitioners without apparent benefit; I at once ordered him to bed, with instructions to keep perfectly quiet. The treatment consisted entirely of alkaline remedies and counter irritation to the perineum, with an exclusive diet of bread and milk. This course was persisted in for several months, and resulted in a complete recovery. Whenever a case of chronic trouble of the bladder or prostate comes into your hands, if you will follow the plan of putting the patient to bed, and thus compelling him to take the necessary rest, he will invariably be much benefited. You must remember that a patient can hardly move, and certainly cannot take a step, without irritating the inflamed prostate and bladder. The prostate in cases of acute inflammation will sometimes be as large as a small orange, and under such circumstances the slightest motion of the thighs will cause mechanically more or less pain and irritation. In addition to this, the perpendicular position will tend to cause congestion and irritation of the inflamed organ, and, as a result, increase the inflammation. It is not only the necessity of physical rest that we must impress upon the minds of our patients, but we must try and secure sexual rest as well. This is of necessity quite difficult to accomplish. A patient

with a broken leg is compelled to take rest —indeed, he cannot move without being punished for his indiscretion; his leg is bandaged and bound in splints, thus rendering movement of the broken limb well nigh impossible. A patient suffering from pneumonia has his chest swathed with hot poultices, thus insuring rest to the inflamed lung. Even in genito-urinary diseases physical rest is comparatively easy of accomplishment, and the patient may often be kept in bed as long as the physician deems necessary. Unfortunately, however, it is much more difficult to keep the patient's thoughts diverted from his sexual organs, which unlike the broken leg or inflamed lung, may be irritated through the medium of the mind. Very many of the morbid conditions affecting the sexual apparatus are due to reflex sexual irritation through the medium of the mind. Very often the patient reads a great deal of literature of a more or less stimulating nature, or allows his mind to dwell upon sexual affairs; and as a consequence the sexual organs are never at rest. I suppose, moreover, that every unmarried man suffers more or less from sexual starvation. The male sex has no monopoly in this respect, for unmarried women suffer from the same difficulty. Only a few days ago a young lady consulted me for this trouble. She informed me that she was annoyed continually by extreme sexual desire, or as she expressed it "excitement." The young lady was intelligent, well educated and refined, and was aware that she had some obscure trouble of the uterus which might account for her ailment. She was averse to an examination, but I concluded inferentially that she had some inflammatory affection of the uterus or ovaries which was causing reflex excitement or sexual hyperæsthesia. She stated that she was greatly annoyed by peculiar, quivering sensations about the uterus, attended by emissions of a fluid of some kind, and occurring daily. You are probably aware of the physiological fact that women do not have emissions during intercourse; what they really have is an excessive secretion of the mucus which normally lubricates the genital tract, and this mucus constituted the "emission" in this instance. I mention this case simply to demonstrate to you the fact that it is not alone the male sex which suffers from sexual starvation, though women are not so liable to understand the true situation as men. A great many females know that there is something the matter with them, but they do not ascribe the trouble to its real source, which is no more nor less than sexual starvation. Hysteria, melancholia, hypochondria, and a great many other nervous conditions in women, may result reflexly from irritation of the sexual apparatus, and irritation of the uterus and ovaries may result from the instinctive physiological craving with which every woman, however pure, is endowed. It may not be recognized, but the necessity for a proper performance of sexual function exists in every adult human being. No man or woman at adult age is in a perfect physiological condition until the sexual function is naturally and regularly performed. It is not merely the sexual act, viz: the orgasm and discharge of semen in the male, or the orgasm and reception of semen in the female that is essential to the relief of this condition, which has been termed "sexual starvation," but there should rightfully be a physiological purpose in the performance of the procreative function, and this is never accomplished except in the matrimonial state. The sexual appetitite of the average man, after two or three years of married life, becomes less active, and, after a while, he ceases to think of his sexual organs to any great extent; in fact, he does not usually concern himself any more than he worries about the function of his bowels or bladder, hence he lives contentedly, as far as his sexual organs are concerned, and performs his family duties in very much the same perfunctory fashion that he goes to stool. Modern society, unfortunately, imposes conditions which render sexual excitement without gratification very common. A young man and woman go to a ball, and while under the emotional influence of the music they squeeze each other more or less in the various figures of the dance, and however pure in mind they may be, these things tend to excite and stimulate their sexual organs, when there are no legitimate means of gratification; the young man, perhaps, is reluctant in popping the question for the simple reason that he considers matrimony too expensive, while the young woman is debarred from taking the initiative by social custom. Literature of a romantic character is even worse than the dance in its exciting effect upon the generative organs of both sexes.

Now, there are ways and means of preventing the injurious effects that are caused by this sexual stimulation without gratification, but fornication is not one of them, for the fear of evil consequences alone will certainly render such a course decidedly unphysiological. Masturbation only serves to make matters physically worse, to say nothing of its demoralizing effects. If I

were asked what I considered the best moral educator for the young man, I should say the gymnasium. You might think, perhaps, that physical improvement would cause the patient to become more active and amorous in a sexual sense; this, however, is not true. The most amorous man is not always the most vigorous one. The man who studies hard, or who is engaged in an intellectual occupation that fosters an excitable state of the nervous system and exaggerates nervous sensibility, is apt to be more intemperate in his sexual relations than the hard-working laboring man. You notice, however, that the laboring man is generally the one who has the most children; it is not the individual who copulates most. The man who copulates the least is usually the one who is best fitted for procreation, because he is, from a sexual point of view, the most energetic. It is a cardinal rule that over-excitement of any function will cause a loss of power. It is quite generally known that the male population of the Orient become impotent at an earlier period than any other race of men, on account of their free indulgence of their sensual appetites. The men and women alike suffer from premature old age on account of excessive sexual indulgence, conjoined with a life of indolence and ease. The man who indulges in sexual intercourse most frequently in his youth is the one who will be most likely to become impotent or sterile when he reaches middle age. This holds true with all peoples the world over. I am very often consulted by men approaching middle age, who complain that they cannot copulate as frequently as they used to, and who ask for remedies wherewith to whip up the jaded steed. To such patients I say: "You are paying for your early excesses, and you cannot expect to do sexual duty as often as you did when but eighteen or twenty years old." This answer, by the way, seldom satisfies them. A great many patients will come to you complaining of real or imaginary sexual exhaustion, spermatorrhœa, or premature old age, and you must know what to say to them. If you do not understand the physiological conditions involved in these cases, you certainly cannot treat them satisfactorily either to your patients or yourselves.

As I have already stated, we may alleviate excessive sexual irritability and desire through the physical system, by giving our patient an occupation which will necessitate muscular exercise, and thus divert his superfluous nervous energy in the direction of the muscles. We may also benefit him through the medium of the mind. We should keep him busy with some occupation which will serve to divert his thoughts from the sexual organs. Literature of an exciting or prurient nature, and association with fast women, must be forbidden. Good literature and the society of refined ladies are, however, a *sine quâ non*. If the individual can see the way clear to get married, it is a good thing for the physician to advise, irrespective of the patient's confidence in his ability to perform the matrimonial act; for impotency in the average young man is a myth, and, as a rule, he is capable of doing as much damage as the next one.

I had a very peculiar experience with one of my young gentleman patients. This young man came to me some time ago complaining of a loss of sexual power, and said that he was engaged to be married, but as he no longer had erections in the morning, he doubted his capacity to perform the marital act, and was naturally much worried about his prospects. I treated him for several months, and with apparent success. He was married in due time, but soon after he sent his wife to see me to ascertain why he could not complete the sexual act. Much to my amusement, I found that she was affected with vaginismus from urethral caruncle. After proper treatment of this condition, things moved on quite serenely. As a rule, your patient will do well, and it is perfectly safe to advise him to get married, if you find the testicles and penis are in a perfectly healthy condition, and he is physically sound in other respects. Marriage is a cure for most of the sexual defects and complaints of young men, and once your patient is happily married, you will hear no more complaints until the babies commence to demonstrate the success of your prescription.

Having presented to you the preliminary subject of genito-urinary and sexual hygiene, I desire to say a few words about the injuries which are occasionally inflicted upon the urethra. We may meet with wounds and contusions of the urethra in any portion of its extent. Contusions and wounds of the pendulous portion of the urethra, however, are rare. It is a rather difficult matter to catch the pendulous portion of the penis in such a way as to damage it, on account of its mobility and varying anatomical relations. Notwithstanding this peculiarity, injury of this portion of the canal occasionally results from falls or blows. It is more apt, however, to occur from unskillful surgical interference. The urethra may be lacerated, contused or incised. We may have a sim-

ple slit in the urethral wall which will result in a fistula of the penile portion of the urethra. We may have extensive extravasation if the urethral walls are injured to any marked degree, and this may be followed by suppuration—in fact it is peculiarly liable to do so, because we have more or less cellular tissue which becomes infiltrated with the urine, and this is apt to result in decomposition with inevitable abscess. If an abscess should occur, it would burrow itself in different directions and cause loss of tissue substance and a consequent urinary fistula. In the case of the deep urethra, we have entirely different conditions, for in this region wounds and bruises are easily produced. Injuries in this region are characterized by gravity both immediate and remote, for whenever a man falls astride a wheel or receives a kick of sufficient gravity to produce injury of the mucous membrane, the accident will almost invariably be followed by organic stricture. An injury of sufficient severity to produce hemorrhage will inevitably be followed by stricture. We have the same resultant morbid conditions and injuries of its pendulous portion, but they are more grave as regards the life of the individual; they are, however, not so strong as regards the danger of the formation of a fistula. The tissues surrounding the deep urethra are thick and dense, and circumstances are favorable to the formation of the granulations which are necessary to the closure of any opening in the canal. In the pendulous portion of the urethra the walls are thin, consequently any loss of tissue will produce a permanent fistula, and a plastic operation for its closure is generally called for. On the other hand, it is in the deeper portion of the canal that extravasation is most likely to produce serious loss of tissue substance, from the fact that there is a large amount of cellular tissue in this location, which is very prone to break down and form sloughs. In any case of injury of the deep urethra, no matter how slight it may seem, the patient is quite apt to have a stricture, and should be so informed.

I now wish to call your attention to the management of these cases. As a consequence of an injury to the urethra, there is likely to be considerable swelling from extravasation of blood; the swelling may be due to this alone, or in part to secondary inflammation. A simple inflammatory swelling may close the urethra completely, even where the extravasation has been quite limited. Whatever the precise condition may be, there results complete retention of urine. Your first impulse on seeing such a case would probably be to pass a catheter; if, however, you pass such an instrument you are liable to make a false passage; you may tear open the urethral walls by the introduction of the catheter, and you thus cause the very thing you hope to avoid, *i. e.*, extravasation. As a word of warning, I would say that in these cases of extravasation of blood with retention you should never pass a catheter unless it becomes absolutely necessary. First try anæsthetics, the hot bath, or morphine, any or all of these antispasmodic agents being indicated, and if they fail to afford relief to the retention, you may try to pass a small soft catheter. If you fail to pass the catheter try a small filiform bougie, and if you succeed with this pass an open end soft catheter over it. Subsequent to relief of the retention, it is necessary to pass instruments from time to time to prevent an otherwise inevitable traumatic stricture. If the urine cannot be drawn off with a catheter, the proper procedure is to make a free median incision in the perineum for the purpose of relieving the retention of the urine, and, at the same time, curing the consequent traumatic stricture. You will always prevent stricture in these cases, if you keep the urethra open properly by the introduction of sounds. Do not be afraid to use the knife in these cases, for the tissues infiltrated by the urine will serve as a focus for pus formation, and prolonged suppuration is apt to cause death from asthenia, to say nothing of the danger of pyaemia or septicæemia. It is a safe rule, therefore, to make free incisions and apply proper antiseptic dressings in all injuries of this character. Where extravasation of urine exists free incisions are absolutely necessary.

In conclusion, I wish to call your attention to the close similarity which exists between the sloughing which results from extravasation of urine, and that produced by cellular erysipelas in this locality. It is hard to say which is most destructive, and most likely to cause secondary sepsis or asthenia. The poison of the rattle-snake is hardly more destructive to connective tissue vitality. The same treatment is proper in both, viz: free incisions, drainage, antisepsis, general and local and free stimulation.

COMMUNICATIONS.

DIAGNOSTIC VALUE OF TUBERCLE BACILLI IN SPUTA.*

BY DR. H. M. FUSSELL,

Of Philadelphia.

In looking over the literature relating to this subject, I have found but few writers among Americans, while the foreign journals of 1883 and 1884 contain numerous articles pertaining to it. At that time the subject was new, and it might be objected that the writers in those years were carried away by the glamour of the subject. That objection, at least, cannot be made to an article written now, five years after Koch's discovery, and more than four years since its application to the examination of sputa.

Without exception the writers spoken of above agree that, as a diagnostic sign of phthisis, tubercle bacilli found in the sputa are of the greatest practical importance.

Heron (*Lancet*, February 3, 1883,) examined sputa from 62 cases, and found bacilli in all but 3. He comes to the conclusion that "the presence of the bacillus of tubercle in sputum is sufficient to fix the identity of certain cases of diseases."

West (*Lancet*, February 25, 1883,) thinks bacilli in sputa may be of diagnostic value in some doubtful cases, but generally they are in confirmation of what is made plain by physical signs.

Williams (*Lancet*, February 24, 1883,) examined 130 specimens of sputum. 21 cases were of various diseases other than phthisis, asthma, bronchitis, etc.; 109 cases of various forms of phthisis; 106 of the 109 cases contained bacilli.

Sée is a firm believer in the diagnostic value of tubercle bacilli in sputa.

Dreschfeld examined 46 cases in which physical signs were marked, and 3 doubtful cases—2 with no physical signs, 1 with an apex catarrh only. He concludes that tubercle bacilli in sputa are of the greatest diagnostic value, but of no prognostic value.

Dicht found bacilli in sputa of all of 12 cases of phthisis.

Heron (*British Med. Journal*, April 28, 1883,) found tubercle bacilli in sputa of 116 cases. In the majority of cases there could have been no reasonable doubt because of the physical signs, but in a few cases where bacilli were found there were but few physical signs.

Marchiafava and Celli are quoted in the *London Med. Record*, of January 15, 1886, as having found Koch's bacillus in sputa of 15 cases of phthisis, in 1 case of slight catarrh of apex, and in one case of hæmoptysis without signs. They failed to find it in 6 cases of chronic bronchitis and 1 case of syphilitic inflammation.

Negri and Pinolini (*London Med. Record*, January 15, 1886) diagnosed phthisis by the examination of sputum, and confirmed the diagnosis by subsequent physical examination.

Voblyi (*British Med. Journal*, 1883,) found tubercle bacilli in sputa of all of 35 cases of phthisis. No tubercle bacilli were found in 18 cases of various other lung diseases. In some of the cases of phthisis the physical signs were at first meagre, but became more evident after a time.

Dreschfeld (*British Med. Journal*, February 17, 1883) examined sputa of 3 cases of hæmoptysis without evident physical signs of phthisis. Tubercle bacilli were found in all the cases.

Prudden (*N. Y. Med. Record*, April 14, 1883) examined 58 specimens of sputa. Tubercle bacilli were present in 46 cases.

Austin Flint, Sr., says the results of the examinations of various specimens of sputa for tubercle bacilli satisfy him that bacilli in sputum may be relied upon as proof of the existence of tuberculous disease.

If repeated examinations made with sufficient care show the presence of tubercle bacilli, the diagnosis of phthisis is positive; and, on the other hand, if on repeated and careful examinations tubercle bacilli be *not* found, phthisis may with much probability be excluded.

"I venture to predict that the time will soon come when, in order to corroborate the diagnosis and as the hinge on which the diagnosis will turn in certain cases, microscopical examinations of the sputa will be considered as much a matter of course as examinations of urine for evidence of renal disease."

My personal observations as set forth below confirm the above opinions, and enable me to reaffirm that the presence of tubercle bacilli in sputa is diagnostic proof of the presence of tuberculous phthisis. In the examination of my cases I used a modification of Gibbe's method suggested by Prof. Wm. Osler.

The sputum was spread as thinly as possible on a clean cover-glass, allowed to dry in the air, and passed quickly two or three times through the flame of a spirit lamp. The cover-glass was then immersed in solution of magenta, manufactured by Beck & Co., and

*Philadelphia County Medical Society, stated meeting, April 27, 1887.

allowed to remain fifteen minutes after first slightly heating. It was then decolorized in alcohol, acidified with hydrochloric acid (four or five drops to a watchglassful of alcohol), and examined under a moderately high power.

In this manner the whole proceeding can be done in less than half an hour. If bacilli were not found by the rapid method, however, the glasses were allowed to remain in magenta over night, and then examined as before. The power used at first was Hartnack No. 9 immersion, afterwards 7 objective, 4 eyepiece. Lower powers may be used, however, by one perfectly familiar with the bacillus. I have used a Zentmayer one-fifth with A eyepiece.

The sputa from 100 cases of lung disease were examined.

For convenience, we may divide these cases into two classes, I. and II.

Class I. contains 84 cases. The sputa of all of these cases contained tubercle bacilli.

Class II. contains 16 cases. Tubercle bacilli were *not* found in sputa from any of these cases.

Each of the above classes may be subdivided:

Class I.

Subdivision A contains 79 cases in which there were evident physical signs of phthisis.

Subdivision B contains 5 cases in which there were few or no physical signs of phthisis. The diagnosis was made by the presence of bacilli in the sputa.

Class II,

Subdivision C contains 8 cases in which phthisis was *not* suspected from the physical signs, and no bacilli were found.

Subdivision D contains 8 cases in which the physical signs led to a suspicion of phthisis, but the absence of tubercle bacilli and the subsequent history proved it to be absent.

It is in such cases as those of subdivisions B and D that the presence or absence of tubercle bacilli in the sputa is of such practical value, and it will be well to take these cases in detail, referring the more curious to the summary attached for an account of each case.

We will first give our attention to the five cases under subdivision B, or those in which the physical signs did not warrant a diagnosis of phthisis, and in which tubercle bacilli were found, the subsequent history proving the correctness of a diagnosis of phthisis made after examination of the sputa.

Case 17. (Summary.) Thomas R., aged forty-one, of good family history. Cough, hectic, and loss of flesh for eight weeks. Physical signs at first examination were entirely inadequate to base a diagnosis of phthisis upon. Examination of sputa at second visit showed the presence of myriads of tubercle bacilli. Afterward, consolidation at right apex developed. The case ran a rapid course, and death took place within the year.

Case 25. (Summary.) May C., aged twenty-one. Both parents dead of phthisis; cough, hectic, loss of flesh. Examination of throat showed the presence of a polypoid growth. Physical signs were inadequate to base a diagnosis upon, though there were some signs of congestion at right apex. Examination of sputa showed numerous tubercle bacilli. Rapid consolidation took place; death in eight months at the Episcopal Hospital.

Case 18. (Summary.) Annie W., aged thirty-five. Husband died of phthisis six months before patient came under observation. She was suffering from extreme dyspnœa and cough. Œdema of feet, having had an attack of general œdema some weeks previously. Examination of chest showed a mitral systolic murmur. The heart was beating very rapidly. The symptoms were attributed to the heart lesion. No signs of consolidation could be found after careful examination. On examination of the sputa it was found loaded with tubercle bacilli. She was admitted to the University Hospital; gradually failed, her chills and fever becoming more marked. Repeated examination of sputa always showed bacilli; finally, signs of consolidation at right apex developed.

Case 20. (Summary.) Mrs. R. Cough, slight expectoration, meagre physical signs. A few tubercle bacilli found. Eight months have passed since the first examination. In the meantime the woman has become pregnant, and her health has improved, though the cough still remains. January 17, 1887, child born; cough returned, sputa reëxamined, bacilli found. More evident signs of consolidation at apex.

Case C. (Summary.) Mrs. H. Good family history. There was an attack of pneumonia three years ago. Since then health has been gradually failing. Now there are cough, hectic, loss of flesh. Slight consolidation at left apex. This woman was taken for consultation to one of the first diagnosticians of the city. The consolidation was recognized, but the case pronounced one of a probable catarrhal character. The sputa

from this case was afterward given to me, and myriads of tubercle bacilli found. April 21, the case has grown rapidly worse, and death is expected daily.

As was stated in the history of these cases, the physical signs did not warrant a diagnosis of phthisis. The examination of the sputa was made because the cases were doubtful and interesting, for the sake of making the diagnosis. Though no better in these instances for the patient, it was a comfort to the physician as a diagnostician when the histories proved the correctness of his diagnosis of phthisis.

No less interesting and instructive than the above are the eight cases coming under Subdivision D, where the history and physical signs gave a strong suspicion of phthisis. No bacilli were found in any case, and complete recovery took place in five of the cases; two became much better, and one died of the results of an acute, and, as I claim, croupous pneumonia.

Case 14. (Summary.) John C., aged sixty-six. For four months there had been cough, hectic, sweats, and loss of flesh. There were signs of consolidation at right *base*. Under treatment the lung cleared up and the man made a good recovery. Repeated examination failed to show bacilli.

Case 1. (Summary.) William R. Family history of phthisis. Cough, some loss of flesh, hectic. Consolidation at left base. No bacilli were found. Under treatment lung cleared up, and one year afterward returned to the dispensary entirely well of lung trouble.

Case 3. (Summary.) Walter L., aged twenty. Good family history. Cough for one month. A sudden, rather profuse hemorrhage. There were slight fever and signs of congestion at left apex. No bacilli were ever found. One year afterward no return of trouble, and seems perfectly well.

Case 8. (Summary.) Alma N., aged twenty-five. Uncle died of phthisis. Cough, with slight loss of flesh for three months. The left apex dull, full of mucous râles, prolonged expiration. No bacilli found after repeated examinations. The lung cleared up, cough stopped, and one year after patient seemed perfectly well.

Case 6. (Summary.) K. H., aged thirty-five, with a good family history, had an attack of pneumonia eighteen months before she came under observation (declares she was perfectly well before). Since then has had cough, hemorrhage, hectic, loss of strength but not of flesh, copious expectoration. On examination a large cavity was found at right apex. Repeated careful examinations failed to show tubercle bacilli. This patient remained under observation for six months, and was in about the same condition as at first. This must have been either a cavity due to breaking down of lung following pneumonia, or, as Professor Flint suggests, one in which the tubercular process had become cured or was dormant.

Case 7. (Summary.) A girl, aged seven. Perfectly well until ten weeks before she came under observation. At that time she had an attack of what was apparently acute pneumonia of the right apex. She did not rally. The lung broke down, and at the time she was seen there was a cavity at right apex. The patient died from exhaustion four weeks after. No bacilli were ever found in sputum.

Case 2. (Summary.) Man, aged twenty-nine, with a family history of phthisis. Had an attack of hæmoptysis in the fall of 1884; during that winter severe cough and loss of flesh. There were physical signs of consolidation at left apex. No bacilli were found after careful and repeated examinations. The man gradually improved, and now, April, 1887, is apparently well, though there is still some dullness at left apex; he is able to work and does not complain.

Case 15. (Summary.) Sallie K., aged twenty-nine. Good family history. About one month before she came under observation began to have cough, fever, pain, rapid loss of flesh. She was found in bed, emaciated, slight fever, 101° F., extreme dyspnœa, diarrhœa, and presented the picture of one in advanced phthisis, indeed such had the case been pronounced. I found but few physical signs. There was consolidation at left base, however. Repeated examination failed to show bacilli. Under vigorous treatment the patient revived and now is perfectly well. Evidently a case of neglected pneumonia.

Of the 79 cases belonging to Subdivision A there could have been no reasonable doubt of the existence of phthisis, basing the opinion on the physical signs present. Tubercle bacilli were found in each case.

Subdivision C contained 8 cases, 2 of chronic pleurisy and 6 of chronic or subacute bronchitis. The sputa from each case were repeatedly examined and no bacilli were ever found.

As most of the cases reported were taken from my service at the University Medical Dispensary, and as dispensary cases, as a rule, are not long under observation, it is impossible to draw any positive conclusions from these cases as to the relation between

the bacillus and prognosis in phthisis; but in cases 17, 19, and 77, which ran a fatal course within a year, and in cases 31, 33, 37, 39, 48, 56, 76, 96, which were examined near to the time of death, tubercle bacilli were unusually abundant. Especially was this the fact in case 56, which was examined about ten days before death. In conclusion I wish to acknowledge my indebtedness to Prof. Osler, to whom I owe my knowledge of the *technique* of the work, and to Drs. John H. Musser, of Philadelphia, and R. R. Bunting, of Roxborough, for opportunity given to examine sputa of their cases.

DISCUSSION.

Dr. Osler said: I think that the importance of the tubercle bacillus in the sputum as a means of diagnosis is not sufficiently recognized by the profession. The technical skill required is not very great, and the time required with the rapid methods of staining is not more than fifteen to thirty minutes. I have succeeded in demonstrating the bacillus within five minutes of the time that the sputum was put upon the slide. This examination is particularly serviceable in just those cases where the evidences of disease are very slight. Only within the past few weeks there was in the University Hospital a man without any pulmonary signs, who had been failing in health and had slight fever. The condition was attributed to some obscure abdominal disease. Finally a suspicion arose that there might be some trouble with the lung, and the sputa were examined and the bacilli found. The signs of phthisis have since developed. The power required for these examinations, as Dr. Fussell says, need not be very high.

TYPHLITIS AND PERITYPHLITIS.

BY T. C. SMITH, M. D.,

Of Aurora, Ind.

Inflammation of the cæcum is of sufficiently frequent occurrence and adequate gravity to merit our serious consideration and careful study. As far as we know, the literature of this disease is not very old. Students a generation or two ago rarely heard of the distinctive title of Typhlitis or Perityphlitis; but though it occurred then as it does now, it was classed with fæcal obstruction, or peritonitis, or peritoneal abscess.

It is now well known, however, that inflammation of the walls of the cæcum does occur, and even of the peritoneum of the right iliac region also, without producing general peritonitis; and though this circumscribed disease is serious, and tends to terminate fatally, it is less fatal than general peritonitis.

Typhlitis may be simply catarrhal, or an ulcerative inflammation may attend it from the inception of the morbid action. At first it is local, and involves only the intestinal tissues. But there is a decided tendency to spread to the peritoneum. Thus a typhilitis, pure and simple at first, is very liable, by extension of the disease, to become the more serious perityphlitis, and even extend to the cellular tissue of the abdomen.

The ætiology of these diseases is of great practical interest. First and notably stands the anatomical relations of the cæcum to the functional duties it is expected to perform. Its peculiar and rather pendant relations render it an easy place for the collection of fæcal masses, foreign bodies, seeds of fruits, biliary calculi, and undigested food. Indeed, impacted fæces, or the lodgment of foreign bodies in the cæcum or appendix vermiformis is but too often the exciting cause of an attack of typhlitis which may end fatally. Such accumulations or lodgments are favored by the peculiar anatomy of the cæcum. Constipation, therefore, in a secondary sense, becomes an ætiological factor in this disease. Mechanical injuries causing typhlitis are not rare. One case that came under my notice, about 1872, was, I think, caused by mechanical violence. Another was caused by a strain resulting from a slip while turning in a path. Another was caused by being thrown from a buggy. Another was, I suspect, caused by a strain in lifting. It is readily produced by blows, as from a plow handle, from a ball, or by a kick.

It is frequently caused by exposure to cold, and is lighted up by a common diarrhœa or entero-colitis. One of the severest cases that ever fell to my lot to manage was in a lad of ten years that had first contracted a severe cold while coasting in the snow; this was followed by an attack of cholera morbus and then by typhlitis. It may also be caused by the use of irritating ingesta, by seeds of fruit, as cherry or plum pits. One case related, as I remember it, by the late Dr. Fries, of Cincinnati, was apparently produced by an apple-seed lodged in the appendix vermiformis—a case of great severity, too, resulting in extensive abscess. One attack renders the subject quite obnoxious to subsequent attacks. One case I treated five times for attacks of this disease. Any considerable freedom in diet or efforts at boyish sports, horseback riding, or exposure to cold,

seemed to bring him down with perityphlitis. He had the last attack, of which I have any knowledge, while attending a medical college in Philadelphia in October, 1876, during which there was suppuration, the abscess opening externally. The lad above referred to was several times threatened with an attack subsequent to the first. Another case coming to my notice in practice had frequent attacks after the first one, which was set up by mechanical injury. A case now in hand has a similar history of repeated attacks. In my experience males are more obnoxious to it than females. This is perhaps due to their greater exposure to cold and mechanical causes.

The pathological anatomy of this disease need not be gone over here, as it is just such as is usually found in cases of inflammation of the bowel and peritoneum, with the variations of ulcerations and abscess in some cases.

The symptomatology is interesting. To diagnosticate the disease early in an attack gives great advantage in the treatment. One will not meet many of these cases before he will discover that it is not easy in every instance to differentiate between it and simple fæcal obstruction at the ilio-cæcal valve early in the attack, or possibly from intussusception. In one case that I saw there was obstruction at the ilio-cæcal valve from a large biliary calculus found after death. The diagnosis was obscure throughout the case. At first there is local pain and soreness more or less acute at the head of the colon. Generally a distinct tumor can be outlined in thin persons. It may not always be felt in persons who are obese. There is a distinct exacerbation, with increased frequency of pulse. Nausea appears early, and a feeling of severe prostration. If the disease arises from an entero-colitis or diarrhœa, the symptoms arise secondarily, and are more severe, but less prominent at first, being obscured by the complications present. There are two distinct varieties: the one catarrhal, the other ulcerative. The symptoms in the former may be more abrupt and severe at the outset, but those of the latter continue the most severe later, and do not yield to treatment as readily, and are quite liable to light up peritonitis, to produce suppuration, perforation, and death, or at best a long tedious course before recovery. The prognosis in the catarrhal type may be said to be fairly good. In the ulcerative variety it is always serious, often very grave. If the case demands opening of the abdominal cavity to remove pus, or a foreign body, then of course it is serious, but may recover. If an abscess opens into the peritoneal cavity, recovery will rarely occur. If it open externally, or into the bowel, recovery may usually be expected in good subjects.

The treatment should in some measure be prophylactic. It is not wise to allow extreme constipation, nor the swallowing of fruit pits that are large, like that of the cherry or plum, or that have firm, large seeds, like apples or melons. They readily lodge in the appendix vermiformis, and set up ulcerative inflammation. But the prophylactic treatment should be most closely observed by those who have been the subjects of one attack. There is a very marked disposition to renewed attacks when once these tissues have been the seat of typhlitis. A large proportion of the cases I have met with or treated have been subject to one or more subsequent attacks. Two cases had each two attacks; one had six or more. In another the subsequent attacks were only prevented by very great care in diet, rest and exercise. I have not yet seen a case where the attack was ever renewed after suppuration has occurred. Where one attack has occurred, any severe mechanical violence is liable to cause its return, such as violent exercise, or labor, or horseback riding, also imprudence in diet or constipation will be quite likely to cause a recurrence at any time within five to eight months after an assault of this disease. To avoid these causes is therefore always wise, until a year has elapsed after being the subject of this affection. The active medicinal treatment, as it seems best to me, consists in anodynes to control the severe pain, a blister, large and free, over the point of inflammatory action, remedies to control nausea and vomiting when present, or diarrhœa when too free. On the other hand, if there is obstinate constipation, the bowels should be freely and easily moved. When there is an accumulation of hard fæces in the head of the colon and typhlitis is present, it must be removed if possible by any reasonable means, for as long as it remains in that location it can do nothing but aggravate the inflammatory process by acting as a foreign and irritating mass. We should be very careful in our selection of a cathartic in such a case. One should be chosen that would produce, not full and scarcely softened passages that will, before ejection, be moved along the colon in almost solid mass, but one that will soften the dried, impacted lump, thin it down as much as possible, and induce its ejection in as easy a way as possible. I know of

nothing that comes any nearer filling these requirements than our common sulphate of magnesia. It is not best, however, to give it in these cases in full free doses all at once, but place an ounce or two ounces in a half pint of water, and give of this a tablespoonful once an hour, or oftener, until it acts. I have never seen any harm, but always good, from this method in cases of typhlitis. In a case recently seen in consultation with Dr. A. L. Loudon, of Wilmington, Ind., this method seemed to act very kindly, and was followed by considerable relief of the most distressing symptom. Shall we use hot or cold applications? If the temperature is very high, use the latter. But I have found only benefit from free blistering in most of the cases I have seen.

It often occurs that nausea and vomiting will interfere with the administration of remedies by the mouth. If needful the anodynes and nourishment can be given usually per rectum. Thus one can combine the anodyne with peptonized beef tea, or can add the bisulphate of quinine if needed. The salts above referred to, can also be used per rectum, and will act as kindly as if given by the mouth, quite as soon and as thoroughly.

I have not yet met with a case where I thought operative procedure needful, unless it may have been the first case I treated. In that instance there was free suppuration that discharged per rectum. Some, as Dr. Gurdon Buck, have recommended early incision where there was evidence of the formation of matter, with a view to be rid of the pus, and prevent danger or death from its discharge into the abdominal cavity. In some cases it is well to operate, and remove pus or any foreign substance that is acting as a mechanical irritant; but it is a nice point to be able to correctly decide just when to use the knife and when to abstain. There is always great risk in opening the abdomen; this alone may cause death. It is well, therefore, "to be sure you are right" before you "go ahead."

REPORT OF A FATAL BURN.

BY BYRON F. DAWSON, M. D.,

of Rochester, Ind.

About 9 o'clock on the morning of April 6th, in the absence of the regular township physician, I was called to attend Alice S., aged 21, an insane inmate of the county poor asylum, of plump form, robust constitution, well nourished, and of previous good health, who two hours before had accidentally ignited her clothes from the stove in the corridor, while given her freedom to eat breakfast. She was perfectly harmless, except as pertained to her own clothing, of which for some time she had completely stripped herself; later, however, she was induced to wear a cotton flannel skirt and a drilling dress by keeping her in a straight jacket, with arms tied behind; these she had on at the time, but wore no underclothes nor shoes.

With her clothes on fire, she walked out of the jail into the yard, and was found sitting on a stone, leaning against the building. A second inmate of the asylum discovering her, protected her head with his coat, and a third dashed a pail of water upon her.

Upon my arrival I found the patient had been transferred to her own bed in a cold room, without any attempt at keeping her covered. She appeared like a maniac, writhing and biting her own hand and forearm, calling "Give Allie one"—the only words she has used in the past fifteen years. I ordered the patient removed to a warm room. Upon examination the following conditions were found: Patient entirely naked except a small portion of the dress waist remaining on the shoulders and neck, covering the scapular, supra-scapular and supra-mammary regions. All the rest had been burned on the body, and this remnant was blackened and charred. The entire body was found burned to the extent of the first four (chiefly 3d and 4th) degrees of Dupuytren's classification, except these small areas: right half of face, back of neck, right shoulders in supra-scapular region, back of hand, soles of feet, and middle third of the back down to the lumbar region; hair was singed. Front thorax, abdomen, and front of thighs were burned to a crisp. Over the greater portion of this vast area the cuticle had been removed by her rolling on the bed before my arrival. Excessive thirst.

At once administered ⅓ gr. morphia sulph. hypodermically, and used a warm lotion of sodii bicarb. (℥ss. to Oj.) over the entire burned area, then anointed the body and limbs with petrolatum. Repeated the injection at 9:30, and again at 12, the patient becoming restless in the meantime. Opium by the mouth was desirable, but hypodermic medication was necessary, as the patient would drink nothing but water from a tin cup. Directed that the patient be given all the cold water she desired.

3 p. m.—Patient under influence of morphine, but when called would rise on her elbow and appear unusually bright, then take a drink of water, and at once relapse into

profound slumber in whatever position she then remained. Pulse small, weak, rapid—could not be counted. Commencing anasarca. Hypodermic injection of ¼ gr. morphine at 4:30 p. m. Has had two attacks of vomiting.

Patient died at 9 p. m. of same day, without recovery from shock. Body in state of emprosthotonos, but from the evidence of the attendants I conclude that tetanus was mild. Rigor mortis occurred within one hour (before the body was "laid out"), and was so intense that extensive laceration occurred in the groin in attempting to confine the body in an ordinary coffin 18 hours after death. No post mortem was held.

At the age of six years the deceased had cerebro-spinal meningitis, sequelæ of which were insanity and aphasia, previous to which the child is said to have been possessed of ordinary intelligence. Some years ago she was severely burned on the abdomen and thighs, which nearly proved fatal, and caused a disfiguring cicatrix. The patient was able to feed herself with her toes when confined in the straight jacket, and had a somewhat extended reputation for her wonderful feats of climbing.

Erichsen says: "In many cases of extreme burn the patient suffers no pain, although perfectly conscious. This is a very grave sign, indicating the severest shock." Whether or not this is true could not be definitely determined in this case, but the superintendent of the asylum says that previous to my arrival this patient was no more restless, and made no more noise than was usual with her, but her actions were certainly maniacal when I arrived. No hope being entertained for her recovery, the large and frequently repeated doses of morphine are explained in the desire to render the patient wholly insensible to pain, that death might be easy.

This case is deemed interesting because of the extent of the burn and the mental condition of the patient.

MEDICAL CASES IN THE COURTS.

BY HENRY A. RILEY, ESQ.,

Of New York.

MEDICAL CONTRACTS.

There was a recent case in the New Jersey Court of Chancery, on the interesting question whether a physician could make an agreement such as to prevent him from ever practicing medicine in a certain locality. It appeared that a physician, intending to be absent from the city of Newark a considerable time, employed another to attend to his practice, but fearing his patients might be lost to him when he resumed his practice, he secured the signature of the attending physician to this agreement: "In consideration of this contract made with him by the said * * * the said * * * hereby covenants and agrees not to engage in the practice of medicine or surgery in the city of Newark at any time hereafter." The employed physician did, after the termination of his engagement, begin practice for himself in Newark, and suit was brought to prevent him from doing so. The answer was that the agreement was an unreasonable one, and was in restraint of trade and void in law.

The court held that the claim was correct, and an injunction should not issue to prevent the physician from practicing for himself.

The main ground for the decision is that the agreement covered too long a period of time; it might be many years after the death of the physician who was supposed to be benefited. On this point the reasoning of the court will be interesting. The judge said: "The fault imputed to the covenant is that the restriction which it imposes is to endure for an unreasonable period of time—for a much longer period than will be necessary for the protection of the complainant. It interdicts the defendant, it will be observed, from practicing medicine or surgery in the city of Newark at any time hereafter. The restraint covers the whole period of the defendant's life, and if an injunction is awarded enforcing the covenant according to its terms, the defendant can never at any time thereafter practice his profession in the city of Newark, though the complainant may the next year or even the next month after the injunction issues lose his life or his reason, or remove to another field of practice. Under such circumstances the injunction would give no protection to the complainant—he would need none; and the only purpose the injunction could serve would be to causelessly oppress the defendant."

ANTE-MORTEM PROBATE OF WILLS.

The question of ante-mortem probate of wills is up again in the New York Legislature, a bill having been introduced in the Assembly. The plan of allowing a person to prove his will while alive, and thus prevent the charge of mental incapacity after his death is a desirable one, if practicable, but it is doubtful if it can be made to work. Comparatively few people will try it, and as has been the case in Michigan, it is probable that a short trial will result in its repeal.

MEDICO-LEGAL ASPECTS OF HYPNOTISM.

Some recent experiments in hypnotism in Paris open up a very extensive medico-legal field of investigation, and suggest possibilities which are most startling. Persons were experimented with, and when they were sufficiently under the influence of the operator they were induced to sign promissory notes, and in one case to execute wills. The person who signed the note was perfectly conscious of doing so, and wished the document prepared with all the proper legal technicalities; she did not, however, know whether she had received the money mentioned in the note or not. The broad field here opened up for possible imposture is most appalling. If an expert in hypnotism, who is also a scoundrel, could induce persons to execute perfectly legal documents and promises to pay, and then attempt to enforce them, it might be exceedingly difficult to present any legal defence to actions based on them. Take, for instance, the case mentioned of the person signing the note: she knew after she was relieved from the hypnotic influence that she had signed the note, but the fact of the receipt of the money was not known, or perhaps it might be more accurately stated that she did not know whether she had received it or not, and did not know whether she had put it away or not.

The opportunity for fraudulent claims is a most inviting one to the accomplished scoundrel, and yet it must be said that there is a new defence made possible to many actions. A person can now admit the making of some obligation, and yet attempt to avoid its effect by pleading the hypnotic condition when making it. This defence might possibly prove as successful as the insanity plea in murder trials.

Hospital Notes.

CHARITY HOSPITAL, NEW YORK.

Stenosis of Larynx—Intubation.

By John J. Reid, of New York.

The case here recorded is of value in demonstrating the great advantage of intubation in stenosis of the larynx.

Dr. Joseph O. Dwyer, after perfecting his laryngeal tubes for use in the croup of children, turned his attention to laryngeal stenosis in the adult, and reported two cases in the *New York Medical Journal*, June 5, 1886.

The following case makes the third on record as far as I am aware: J. K., aged 22, entered hospital May 1, 1886, and stated that four years previously he contracted a cold which was accompanied by hoarseness. He had been under observation at a dispensary, but, from his statement of the case, had paid little attention to his disease. He steadily became worse, and on admission to hospital there were hoarseness, cough, and dyspnœa at night. He gave no direct history of syphilis, but there was a necrosis of the hyoid bone which could be readily made out on examination of the throat. From the orifice of the sinus leading to the necrosed hyoid on the right side, there was ulceration which extended around the base of epiglottis, and down towards the vocal cords.

The cords had only limited motion. There was no marked dyspnœa on entrance to hospital, but by degrees it became pronounced, especially at night.

September 20. A small tube was introduced, but coughed up after 21 hours. The dyspnœa was relieved in the meantime.

September 21. A large tube was retained for 24 hours.

September 22. A still larger tube was inserted, and was coughed out after one-half hour.

No tube was introduced for several days to mark the effect. It was found that the dyspnœa was much relieved at first, but gradually disappeared.

September 29. A still larger tube was introduced, and retained for 18 days, when it came out whilst the patient was sitting up.

During the wearing of the tube there was no special discomfort complained of, regardless of the fact that the shoulder of the tube rested on an ulcerated surface of the larynx above the vocal cords. There was no marked improvement in the voice. Dyspnœa did not return until December, when there was slight evidence of it.

December 15. Introduced the same tube for 24 hours, when it was removed with an extractor.

The benefit then obtained was continued till the patient left hospital to resume work as a cigarmaker. He has not reported since, and the inference is that he has suffered no serious trouble up to the present date, April 30, 1887.

—The students of the University of Paris numbered nearly 11,000 last year. Of these, 3,786 were studying law, and 3,696 were studying medicine, while only 35 were studying theology. The female students numbered 167.

Medical Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated meeting, April 27, 1887. H. Augustus Wilson, M. D., in the chair.

Dr. G. Betton Massey read a paper on

A Rheostat, for the Utilization of Incandescent Lighting Currents in Medical Practice; also a Cheap, Permanent Galvanic Battery.

The new building of the Orthopædic Hospital having been recently furnished with an incandescent lighting plant for which wires were laid throughout the edifice, I determined to make use of the same current in the treatment of patients in different parts of the house, in place of that derived from ordinary galvanic batteries. To do this, it was necessary to use the current as it was delivered to the lamps in full strength from the entire secondary battery, as the many wires necessary to the use of a cell selector were out of the question. The electromotive force of this current is only 60 volts, which is about equal to the full strength of an ordinary gravity battery of 60 cells, or of a Grenet battery of 45 cells. It is readily seen, therefore, that I had merely to choose a rheostat or resistance medium that would be efficient with the full strength of any good chemical battery. The wire rheostat was rejected for the double reason that it was expensive, and did not admit of delicate gradations; and the water tube, because it would have to be long to be efficient, and with the rod pulled up would be awkward in use.

The rheostat exhibited to you to-night is free from all of these objections, and is, as you see, an exceedingly handy instrument. It consists merely of a broad line of pencil mark on roughened glass extending around the greater part of a circle.* One end of this broken circle of pencil mark is connected with a terminal of the battery, and the circuit is completed by a circular switch which makes contact with the pencil mark by means of a small metallic wheel. A greater or less length of plumbago is thus included in the circuit with ease, and this material thinly spread out being a poor conductor, a great range of resistances is obtained. In connection with the rheostat, a milliampèremeter must always be used, the hand being on the rheostat and the eye on the meter. With this rheostat and a meter attached to a battery, all cell selectors may be dispensed with, and the whole battery used simultaneously and evenly. The instrument before you has been constructed by Mr. Flemming, and is elegantly mounted with the meter on a ward table for use at the bedside. Connection with the mains is made by thrusting a plug attached to the table into receptacles in the base boards near each bed in the wards and beneath the lamps in the private rooms.

I have also to show you to-night a new galvanic cell devised by myself for use in a permanent cabinet or shelf battery. Its chief advantages are: the cheapness of the materials used, its freedom from local action and creeping salts, and the long intervals that it will run without being touched. It consists of a zinc rod, such as is sold for use in the Leclanché cell, clasped by rubber bands to a carbon rod, and resting in a satuated aqueous solution of chloride of ammonium and bichromate of potassium. The carbon rod is one of those used in arc light lamps, and, like the zincs, is both plentiful and cheap, one carbon rod broken in half serving for two cells. The containing jar is an ounce quinine bottle, such as sold by Powers & Weightman. Before attaching the wires to the carbons by winding and twisting, as shown in one cell, or by the pin-and hole arrangement, as shown in another, the tops of the carbons must be treated with boiling paraffine to prevent interstitial creeping. The elements are kept about half an inch apart by blocks of soft rubber. The permanence of the cell is greatly improved by greasing the inside of the necks of the bottles and covering each with a piece of thin rubber to prevent evaporation. Sixty cells give a strong and reliable battery, and I would estimate the electro-motive force at fully a volt per cell. The total cost of the materials is only twelve cents per cell.

DISCUSSION.

Dr. C. Seiler said: Some months ago Dr. Massey called my attention to the form of rheostat which he has presented to-night, which was a modified form of one exhibited by Dr. Jacobi at the meeting of the American Neurological Society, three years ago. Looking up the subject, I found that a similar contrivance was suggested by Professor Philips, in the *Philosophical Magazine*, 1870, No. 46, page 41. He shows that such a rheostat will not answer for accurate measurement, as moisture and other conditions affect the resistance in the course of a few days. For medical purposes, however, this variation

*A straight pencil-mark rheostat was shown by Dr. Jacobi to the American Neurological Society in 1885.

is so trifling that it does not amount to much. The only objection that I can see to this instrument is that the current has to leap from one particle of plumbago to another, for, with the microscope it will be seen that the particles do not join each other. I am now trying to arrange the rheostat so that the plumbago will be continuous.

Dr. Massey said: The apparatus described by Dr. Jacobi was straight instead of circular in form. The failure of the instrument to record the same amount of resistance on different days is of no importance, as we must rely upon on the milliampèremeter to register the strength of the current. It is entirely unnecessary to graduate these current controllers in any way, as their only use is to vary the strength without shock. In reply to Dr. Seiler's remarks about the current leaping from particle to particle, I would remark that all the effects of the currents traversing these pencil marks, show that they do not differ from other continuous currents through any other media. The objection to a graphite line that would be continuous under the microscope, is that it would not present enough resistance to be of service.

NEW YORK PATHOLOGICAL SOCIETY.

Stated meeting, April 27, 1887.

T. Mitchell Pruden, M. D., President, in the chair.

Anthracosis Pulmonum.

Dr. Peterson presented the lung of a man sixty-seven years of age, a laborer in stove-works. The room in which he had been employed contained an atmosphere loaded with carbonaceous matter and fine sand. This he had inhaled for thirty-one years. His wife said that he had suffered from a terrible cough. Death took place suddenly when he was walking in the street, and the autopsy revealed the cause to be fatty degeneration of the heart. But the point of interest in the case was the condition of the lungs, which were nearly the color of coal throughout; the fresh-cut surface stained the finger black. There were lobules converted almost completely into fibrous tissue filled with carbonaceous matter. In one lung was an abscess the size of a hazelnut. There were numbers of men working in the same room, all of whom suffered from some pulmonary trouble.

Renal Calculus.

Dr. I. Van Gieson exhibited a large white kidney containing a calculus in its sinus. The calculus was 5 cm. long, 1 cm. in diameter, and had two branches each about 1 cm. in length, which extended into the calyces.

Phosphorous Poisoning.

Dr. Van Gieson also presented specimens from the body of a man who died four days after drinking water containing phosphorus. There was slow respiration and jaundice. The autopsy showed fatty degeneration of the heart and parenchymatous degeneration in the kidneys. Mucous membrane of the stomach was nearly normal in some places, in others there were erosions. In some parts the cells on the surface and those in the follicles were swollen and granular. In the duodenum the epithelium of Brunner's glands was swollen. The cells of the pancreas were swollen. The cells and mucous glands of the trachea were swollen and granular.

The case was a typical one of phosphorus poisoning, but it contained two interesting features. One was a very limited area occupied by miliary tubercles, they being found in only one of the bronchial glands. There were no tubercles elsewhere. In the course of time the patient might have developed general tuberculosis. The other point of interest related to hemorrhages from the lymph channels in some of the cervical glands.

The President remarked that this was one of several cases in which he had seen actual fat droplets in the liver cells after phosphorus poisoning. He was disposed to think that the old distinction between fatty degeneration and fatty infiltration was not borne out by experience.

Diphtheria.

Dr. Brothers presented a part of the air-passages of a child nineteen months old, which had died of diphtheria. When Dr. Brothers first saw the child it was suffering from croupy breathing and developing cyanosis. There was limited consolidation of the lung. No false membrane was visible. An O'Dwyer tube was introduced into the larynx. This relieved the impending symptoms of suffocation, but the patient died about two days later. At the autopsy a false membrane, not removable, was found in the larynx, trachea, and larger bronchial tubes. The tonsils and upper pharynx were free. There was slight pneumonic consolidation in either lung. The case did not in the least speak against intubation.

Cirrhosis of the Liver, etc.

Dr. Frank Ferguson presented several organs removed from the body of a man who

had been a heavy drinker for about twenty years. He was healthy until three years ago, when he began to complain of occasional swelling of the feet, headache, and specks before the eyes. Three weeks before death his legs became greatly swollen, his abdomen enlarged, and his scrotum was distended to the size of an adult's head. He was admitted to the hospital semi-comatose. The autopsy, which was made just before the exhibition of the specimens, showed chronic diffuse nephritis and intense congestion of the kidneys; great hyperæmia of the stomach and thickening of its lining membrane. The heart was anæmic, its left ventricle was greatly hypertrophied, but its valves were normal. The liver was cirrhotic, and seemed to be composed almost entirely of fibrous tissue. The scrotum contained a great amount of fat, and enclosed two large lipomata. The testicles were normal. The pancreas was unusually firm. Rarely did one encounter fatty degeneration of the renal capsules so distinct as in this case.

The Society adjourned.

Editorial Department.

Periscope.

The Irritable Heart of Civil Life.

At the stated meeting of the Toronto Medical Society on April 14, 1887, Dr. William Osler, of Philadelphia, read a paper with this title, of which the following abstract is from the *Canadian Practitioner:*

This condition, though not so dangerous to life as organic disease, often gives rise to great discomfort and uneasiness. The prominent symptoms are palpitation, pain, dyspnœa, and slight enlargement. The condition is comparable to the irritable heart mentioned by Da Costa as occurring in military life, particularly among young recruits.

As regards the condition under consideration, the following is the etiological classification:

1. Toxic cases.
2. Those traceable to over-exertion.
3. Those due to sexual excesses.
4. Those accompanying neurasthenia.

The toxic agents giving rise to irritable heart are tobacco (which is the most common), tea and coffee. Young men from 18 to 25 years are most frequently the subjects of irritable heart. There is usually some slight enlargement of the organ, and the symptoms accompanying this are palpitation on exertion, more or less pain, and occasionally dyspnœa.

The reader of the paper then recited several cases illustrating this condition. The principal points in treatment were removal of the cause, rest in bed, and pot. brom. gr. xv. *ter die.* Most of the cases recovered completely.

Irritable heart from over-exertion, otherwise known as heart-strain or heat-shock, is met with in gymnasts, as runners, rowers, etc. There are two forms of heart-strain:

(1) Acute dilatation (heart-shock) the result of an individual great and continued effort. In such cases perfect recovery never takes place, and the subjects are thereafter incapacitated for any great effort.

(2) The irritable heart is the result of persistent and repeated great exertions. This is the condition described by Da Costa as occurring in young soldiers. Gradual hypertrophy and dilatation may precede the irritability. These conditions are sometimes classified under the head of idiopathic hypertrophy and dilatation. Cardiac dropsy and murmurs may be accompanying symptoms. Chronic alcoholism and syphilis, as well as over-exertion, enter into the causation.

Sexual excess, either in the form of coitus or masturbation, induces irritability of heart. The following case is illustrative: A male, aged 26. History good. Had chewed tobacco moderately but never smoked to excess. Had lifted a good deal. Had been a masturbator and also of late had indulged in sexual excess with women. The heart-beat was hard, but not rapid when at rest. There was considerable pain in the chest. Fluttering at night was a distressing symptom. The pulsations were very variable. In recumbent posture the pulse was 74; when erect, 132. There was no murmur. Under treatment here covered in about three months.

The cases of irritable heart, occurring as a result of neurasthenia, are nearly twice as frequent in females as in men. They are accompanied by mental distress, debility, nervous dyspepsia, and, in women, uterine disease. There is sometimes a peculiar vaso-

motor disturbance, causing flushing or even lividity of various parts of the cutaneous surface. A feeling of impending death is a frequent and most distressing symptom in some cases.

Two other conditions, tachycardia, in which the pulsations reach 180–200, and Graves' disease, are forms of irritable heart.

Treatment.—Perfect rest in the recumbent posture, careful feeding, and removal of the cause, are important. The application of cold (50° or 60° F.) to the præcordia, by means of Littré's tubes, frequently allays the pain and rapid action of the heart. Galvanism has been used with some benefit in the tobacco heart. Of drugs, bromide of potassium, in doses of gr. xv. *t. d.*, has been found signally useful. Nux vomica is also beneficial. Aconite and digitalis seem to have no special influence over this condition.

Discussion.— Dr. Graham considered that among toxic agents might be mentioned those formed in the system, especially in patients of the gouty or rheumatic diathesis. In these cases large quantities of starchy or saccharine foods, or even small quantities of alcohol, give rise to extreme irritability of the heart.

Dr. Bryce had met cases in which saccharine and starchy food caused distressing cardiac symptoms by distending the stomach.

Dr. Wilson had used nitro-glycerine and ammonia in such cases with benefit.

Dr. Zimmerman found that emp. belladonnæ over the præcordia often gave relief. Arsenic and cod-liver oil were also found beneficial. In cases of irritability due to distension of the stomach small doses of ac. carbolic are useful.

Right Upper Canine Tooth in the Left Orbit.

Dr. John Ward Cousins reports, in the *British Medical Journal*, April 23, 1887, a very interesting case of a child, 2 years old, from whom he removed a tumor of the left orbit, which proved to be a supernumerary and misplaced right upper canine tooth. The crown of the tooth was enclosed in a sac, and the fang was attached to the orbital plate by fibro-cartilage. On examination the teeth in the mouth were found in normal position, complete in number, and well formed. The jaws were also large and fully developed for a child 2 years old.

Irregularity in the number of teeth may occur in either the first or second dentition, and supernumerary teeth may spring up in any part of the dental arch. In shape these teeth are generally irregular and conical, and they bear no special resemblance to any kind of normal teeth. Sometimes, however, they present a definite outline and accurately resemble one of the recognized forms. Instances of supernumerary incisors, canines and bicuspids have been recorded, but examples of ill-shaped teeth, without possessing the characters of any special form, are of frequent occurrence in dental practice. As regards the time of eruption, supernumerary teeth are always irregular. They are generally matured long before the appearance of the permanent set, but their exact relation to the normal teeth is not well defined. They may be freaks of development in connection with either the temporary or permanent teeth. A normal permanent and a supernumerary tooth sometimes seem to hold the same relation to each other as the teeth of the first and second dentition. In the case of Dr. Cousins there was no irregularity of the teeth, but the age of the patient, and also the special characters of the tooth, clearly indicate its relation to the deciduous set.

Cases of misplaced teeth, in strange situations, have often been recorded. These irregularities, however, are not associated with any special shape of jaw, or deficiency of size in the dental arch. The teeth are generally found to occupy an inverted position on the bone to which they are attached. They have been erupted in the hard palate and in the nares, but Dr. Cousins has been unable to find an instance on record of a tooth appearing in the orbit. The occurrence of a *right* upper canine in the *left* orbit is certainly singular, and this crossed displacement must have taken place at a very early stage of embryonic life. The canine papillæ appear in the primitive dental groove about the eighth week; and soon after the rudimentary pulps of the milk teeth are in rapid formation within their follicles on the edge of the jaw. At this period, a supernumerary follicle and its contents could be very readily displaced from the lip of the primitive groove, as the surrounding tissues are soft, and the rudimentary orbit and the gums are in close proximity. A supernumerary tooth-sac must always be especially liable to dislocation; and when once it gets out of the groove it may be pushed in any direction during the formation of the surrounding structures.

Epidemic of Exudative Tonsillitis in Children.

Thomas F. Raven, L. R. C. P., reports in the *Practitioner*, April, 1887, observations in regard to an interesting epidemic of exudative tonsillitis (diphtheria?) at Broadstairs.

During August and September, 1886, nearly sixty cases of exudative tonsillitis occurred, and for two months later occasionally a mild case would crop up. Almost all of them were extremely uniform in symptoms and progress, and the main characteristics were a high initial temperature, sometimes reaching 105°, flushed face, membranous patches upon one or both tonsils, pyrexia, lasting from five to seven days, clearing up of the throat appearances, convalescence, frequently succeeded by relapse (almost certainly the result of re-infection), eventual recovery, without paralytic sequelæ, or loss or impairment of the reflexes. A condition of considerable anæmia and debility generally supervened, lasting for some weeks. Albuminuria was never found, and glandular enlargement was always absent.

Following ill-marked throat symptoms, three cases of acute rheumatism, with cardiac complications, presented themselves. Permanent valvular mischief resulted in each instance.

The treatment of the tonsillitis was simple, and in every case satisfactory. A solution of chlorate of potassium was freely administered, and as much air and space as could be afforded was given to each patient. While pyrexia lasted, the diet was light; subsequently it was more substantial. For the acute rheumatism, salicylate of sodium was employed, but it entirely failed; and, beyond the administration of alkalies, the treatment was of an expectant character. During convalescence, steel and quinine were required for all the patients.

Mr. Raven gives a brief and interesting review of the various theories in regard to the nature of diphtheria, and concludes that this epidemic was not one of this disease. The sudden onset and the high initial temperature, found in every case, stood in marked contrast to the depressed or scarcely elevated bodily heat, and the insidious and stealthy approaches of diphtheria. The fact of the absence of albuminuria and of glandular swelling at the angle of the jaws; that among so many cases there was not an instance of extension of the membrane to the larynx; that not a single death occurred; that in no case did any paralytic affection or loss of reflexes ensue, is against the assumption that this epidemic was one of diphtheria.

It is, as Mr. Raven remarks, difficult to prove a negative; and it might seem a higher aim to show what diphtheria is than to show what diphtheria is not. Still, experiences of this kind, if faithfully recorded, may assist in determining the truth with regard to this important question.

Dr. Lauder Brunton and Homœopathy.

Faithful to his promise, Dr. Brunton has taken advantage of the opportunity afforded him by the appearance of the third edition of his work on Pharmacology, Therapeutics, and Materia Medica, to repudiate the charge which interested parties have brought against him of having appropriated homœopathic remedies (?) without so much as a word of acknowledgment. He points out that homœopathy consists, not in the possession of this or that medicinal agent, but in the principle upon which it is used. The mere fact that certain drugs were or were not first employed by men professing to practice on homœopathic principles is altogether irrelevant, and beside the point. Just as homœopaths can prescribe mercury or opium in homœopathic doses, and in accordance with Hahnemann's formula, so an ordinary practitioner can employ actæa racemosa or any other drug upon which homœopaths pride themselves without rendering himself amenable to the charge of trespassing on reserved ground. The essence of homœopathy as established by Hahnemann, says Dr. Brunton, lies in the infinitesimal dosage and the universal application of the rule *similia similibus curantur*. It is the falsity of the claim which homœopathy makes, to be in possession, if not of the universal panacea, at least of the only true rule of practice, that makes homœopathy a system of quackery. It is to be hoped that in face of this emphatic disclaimer, those persons who have for some time past striven to claim Dr. Brunton as "one of theirs" will cease their machinations, which can serve no useful purpose and are at most a source of annoyance. This very question was exhaustively discussed in our columns some few months since, on substantially the same grounds as have now been authoritatively put forward by the eminent therapeutist.—*Medical Press and Circular*, April 20, 1887.

Ligation of the Innominate.

Thomas Henderson, M. B., C. M., writes from Rome to the *Lancet* of April 30, 1887:

The patient, a man of about forty-five years, was suffering intense pain from pressure by a very perceptible aneurism of the second part of the right subclavian. Other means having been tried with no good result, Professor Durante, of Rome, deter-

mined upon ligation of the innominate. Accordingly, on March 25 the operation was performed, with strict antiseptic precautions, the vessel being tied in two places, viz., immediately below the junction of the subclavian and common carotid, and again slightly lower down. The vertebral artery was also tied. The ligature used was No. 3 carbolized catgut. The result, up to the present date (April 5) has been most satisfactory. Circulation in the right upper limb and side of the head has been completely restored, and the patient's general health is good, with the exception of obstinate constipation, which may account for a rise of temperature having occurred. The external wound, excepting a small drainage aperture, has healed by first intention.

Pickle for Pathological Preparations.

We are informed that Professor Grawitz, of the Berlin Pathological Museum, has since April, 1885, been making use of a pickling liquid for the preservation of pathological specimens, and after two years' test speaks enthusiastically of its usefulness. The liquid is prepared as follows: 150 grms. of common salt, 40 grms. of sugar, and 20 grms. of saltpetre are dissolved in 1 litre of water. This solution is acidulated by the addition of 3 per cent. of boric or tartaric acid. The acid is necessary on account of the decomposition of the hæmoglobin in the tissues. When the preparation is placed in the liquid, water is added until the object sinks in it. The pickle is ready in from four to eight weeks, when the objects are taken out and placed in fresh clear pickle. The quantity of water that requires to be added is from one-third to one-half. The vessels should be filled brimful, so that when the cover is placed on, no layer of air should remain under the cover; the cover should touch the liquid.

Evisceration of the Eyeball.

The operation of Dr. Mules, of Manchester, consists in emptying the sclerotic and inserting a glass globe in the place of the contents of the eyeball. Mr. W. P. Keall, of Bristol, has modified this by substituting a hollow silver ball for the glass globe. The operation is performed in the usual way under antiseptic precautions. The cornea and adjacent ring of sclerotic are excised, the contents of the eye removed, and the internal surface of the sclerotic scraped clean. A horizontal incision of about five millimetres on either side of the sclerotic permits the hollow ball to be fitted in, and the sclerotic is then stitched together, and the conjunctiva sewed over the whole. The results of his cases show that the silver ball is tolerated perfectly by the living tissues, and that a somewhat violent accidental blow on the eyeball after the operation produced nothing more serious than an ordinary "black eye." The cost of a silver ball is four shillings.

Sialorrhœa of Pregnancy.

M. Schramm reports a case of sialorrhœa in which, after seven hypodermic injections of pilocarpine in one centigramme doses, the salivary flux diminished but did not cease. Bromide of potash was then prescribed, and the salivation ceased. M. Schramm believes that the bromide diminishes the excitability of the glandular nerves and paralyses the secretory fibres of the sympathetic, and the radicular filaments of the facial. One recommendation is its harmlessness to pregnant women.—*L' Union Médicale.*

Latent Pleurisy.

At a recent meeting of the Société Médicale des Hôpitaux, M. Delore presented a patient who had suffered from purulent pleurisy for three years without much inconvenience. M. Delore gave a short summary of the case, and sketched the principal characteristics of latent purulent pleurisy. The general symptoms were determined by the degree to which pus was absorbed; when the thick shell formed by the false membranes prevented absorption, no constitutional symptoms were produced.

Ointment for Ocular Neuralgias.

For the relief of severe-orbital pain following iritis, hyperæsthesia of the retina and neuralgia of the eye-balls, Dr. L. Webster Fox of Philadelphia prescribes the following ointment, which, he informs us, he has found to be of exceptional utility:

R.	Morphia sulph.	gr. iv.
	Chloral	gr. x.
	Cocaine	gr. xx.
	Menthol	gr. xxx.
	Lanolin	℥j.

Sig.—Apply a piece the size of a hazelnut to the temple and over the brow every hour.

—At the annual meeting of the Suffolk District Medical Society, held Saturday evening, April 30th, Dr. John Homans was elected President, and Dr. George W. Gay, Vice President for the ensuing year.

Reviews and Book Notices.

BOOK NOTICES.

A Clinical Manual of the Diseases of the Ear. By Laurence Turnbull, M. D., Ph. G., Aural Surgeon to the Jefferson Medical College Hospital, etc., with a colored lithographic plate, and numerous illustrations on wood. Second revised edition. Philadelphia. J. B. Lippincott Company, 1887. Price, in cloth, $3.00.

It is as rare as it is pleasant to be able to record the publication of a new edition (of increased size) of such a work as the one before us, at a reduced price. Both publisher and author are to be commended for this departure. The work contains a new introduction, treating of the general pathology of ear diseases, the malformations and congenital defects of the ear, and on the auricle. The succeeding 420 pages remain unchanged, being reprinted from the old plates. Then follow 14 pages on deaf mutes, their education, and the prevention of mutism. The articulation method of teaching which is now in almost universal use, is well treated of in the work. Mr. Currick's method of education by means of the double mouth-piece ear trumpet, is not referred to, although its special value has been demonstrated. Chapter XX, a review of the causes and most successful treatment of the more frequent diseases of the ear, has been rewritten, and is especially valuable to the general practitioner. Chapter XXI, on desquamative inflammation of the meatus, the membrane and the middle ear, is new; it bestows necessary attention upon a class of cases which appear to have become more frequent. Chapter XXII is on syphilis and mumps as causes of internal ear disease, on opening of the mastoid, and on malarial otitis. There is so much ground to be covered in these 24 pages, that several chapters might easily have been devoted to it. The ophthalmoscopic examination in mastoid disease, to which the author devotes a page, is very important. The author's experience with the sulphide of calcium treatment in mastoid disease was entirely negative, and he advises opening of the mastoid in every case where we are reasonably certain that cerebral disease is due to caries, or to the retention of pus in the mastoid antrum, or the mastoid cells. There are many who would hesitate to open in every such case, but there are but few who differ with the author concerning the uselessness of the calcium sulphide treatment.

In the appendix cocaine as a local anæsthetic is considered; the author has found it useful in large polypi, and in smaller growths it has "invariably proven valuable." In such cases it usually is valuable, but there are cases where it exercises no effect whatever. Peroxide of hydrogen is next considered, and its value is well illustrated. Sexton's operation for the relief of chronic inflammation of the middle ear is condemned, we believe with justice, the risk being considered as too great. Diphtheritic inflammation of the nose as a cause of deafness, and artificial membrana tympani are next considered, following which are 20 pages on the best means of illuminating the ear, nose, throat and eye, in which the author concludes that the electric light is the best, but regrets that at present it is practically unattainable.

As a whole the book before us is very valuable, and unlike many other so-called clinical manuals, is truly deserving of the title; numerous cases are given in almost every division of the book, but nowhere is the subject better illustrated by cases than in the three new chapters. L. J. L.

Tracts on Massage, No. III—The Uses of Massage in Medical Practice. Translated from the German of Reibmayr, with Notes by Benjamin Lee, A. M., M. D., Ph. D., Secretary of the State Board of Health of Pennsylvania, late President of the American Academy of Medicine, Member of the American Medical Association, etc. Philadelphia, 1887.

This constitutes the third of a valuable series of short tracts which Dr. Lee proposes to issue for the benefit of the busy practitioner, and contains the substance of a useful little treatise by Dr. Albert Reibmayr, of Vienna, entitled "Massage and its Utilization in the Various Departments of Medical Practice." The present tract will shortly be followed by others on the Uses of Massage in the practice of "Surgery," "Midwifery," "Gynæcology," and "Ophthalmology." A bibliography will be appended to each tract for the accommodation of those who desire to procure their information at first hand.

Evacuant Medication. By Henry M. Field. M. D., etc. 8vo., pp. 288. P. Blakiston, Son & Co., Philadelphia, 1887.

In the older days of medicine, the study of cathartics and emetics was carried to an extreme of minuteness, and, indeed, purging and vomiting were the aims of a large share of the medication employed. Of late

years there has been, perhaps, too little attention paid to such agencies in therapeusis. Dr. Field, therefore, who is Professor of Therapeutics in Dartmouth Medical College, has carried out a timely scheme in selecting emetics and cathartics as a theme for a monograph. He treats the subject with reasonable fulness, though rather from the observations of others than from any new experience of his own. Nevertheless, his essay is a judicious condensation of what is most certainly known of the physiological and therapeutic action of these elements of the materia medica.

A Manual of Weights and Measures. Second edition, revised. By Oscar Oldberg, Ph. D. 8vo. pp. 246. Charles Johnson & Co., Chicago, 1887.

This convenient little manual has already proved very useful to students of pharmacy and of medicine, and the author has availed himself of the opportunity afforded by the call for a new edition to give his work a careful revision. It will doubtless still be found by many classes of students a very convenient aid to the memory.

A Practical Treatise on Impotence. Sterility and Allied Diseases of the Male Sexual Organs. By Samuel W. Gross, M. D., etc. Third edition, thoroughly revised. Lea Brothers & Co., Phila.

This interesting and valuable work is the result of a large experience in the treatment of disorders of the genito-urinary apparatus. Its success is indicated by the fact that it has so soon reached a third edition. To handle a subject of this kind well, requires great skill and judgment, and these qualities have been exercised in the book before us, which we can heartily recommend to our readers.

Persistent Pain after Abdominal Section. By James B. Hunter, M. D., Surgeon to the Woman's Hospital, New York, Professor of Gynecology in the New York Polyclinic, etc.

This is an interesting paper. At its close the following conclusions are presented:

1. That all cases of abdominal section done for the relief of pain should be carefully followed up and observed, or made the subject of inquiry, for at least two years from the time of operation, and not counted as cured because the operation itself does not prove fatal.

2. That peritonitis in any degree after operation is to be dreaded as much for its remote consequences as for the immediate danger it threatens.

3. That extreme caution is demanded as to undertaking operations where the history or the physical condition points to the existence of chronic peritonitis.

4. That secondary operations, though sometimes justifiable, are generally of no avail; that they only occasionally afford temporary relief, and very rarely effect a cure.

5. That a guarded prognosis should be made in all cases of abdominal section done especially for the relief of pain; that the patient should be made fully aware that there are certain chances, which it is impossible to calculate, that a perfect cure may not result from even the most successful operation.

Neuritis Plantaris. A Clinical Record. By C. H. Hughes, M. D., St. Louis, Former Surgeon U. S. A.; Superintendent and Physician-in-Chief, Missouri State Lunatic Asylum; Lecturer on Neurology, St. Louis Medical College, etc.

A valuable discussion of the therapeutics of the affection named, with special reference to the applications of electricity.

The Scientific Rationale of Electro-therapy. A Revised Paper on the Therapeutic Applications of Electricity. By C. H. Hughes, M. D., St. Louis.

Tennessee State Board of Health Bulletin for the month ending March 31, 1887.

Report of the Committee on Disinfectants, presented at the fourteenth annual meeting of the American Public Health Association, held at Toronto, Canada, October 5–8, 1886.

A full account of the various methods of practical disinfection, with illustrations of apparatus employed.

A New Explanation of the Renal Troubles, Eclampsia, and other Pathological Phenomena of Pregnancy and Labor. Read (in part) before the Wash. Obst. and Gynec. Soc., Feb. 4th, 1887. By A. F. A. King, M. D., Prof. of Obst., etc., in the Med. Dept. of Columbian University, Washington, D. C., and in the University of Vermont; president of the Washington Obstet. and Gynec. Soc., etc.

The author maintains that the recognition of an oblique, dorso-anterior position of the fœtus above the pelvic brim, during the later months of pregnancy, as the truly *physiological attitude* in both primiparæ and multiparæ, will open a door for the philosophical explanation of phenomena that have hitherto been puzzling and inexplicable both in the domain of pathology and physiology.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called to the ***QUARTERLY COMPENDIUM,*** which we publish. It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician. It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance for the year.

Address **Drs. RANDOLPH & DULLES,**
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

EVACUATION OF PSOAS ABSCESS.

Edward Owen, M. B., F. R. C. S., discusses in the *British Medical Journal,* April 23, 1887, the treatment of psoas abscess, and criticises the let-alone method which was formerly so much adopted. The hope that a psoas abscess might disappear spontaneously he shows to be delusive, as this actually occurs in so small a proportion of cases that it is but a forlorn hope. In a large practice, covering many years' service in a general and a children's hospital, Mr. Owen has known this to happen only once. Even aspiration he thinks to be of no service. The only method which offers a hope of good results is free opening and thorough evacuation, and this should not be postponed until the abscess has reached the surface and thinned the skin. The abscess should be attacked as soon as treatment has brought the patient into the best possible condition for the ordeal. There should be no useless temporizing, and the operation should not be delayed until the skin has become thin and red, for during this time the pus may hollow out for itself a chasm extending from the diaphragm to Scarpa's triangle, and may insinuate itself beneath the iliac fascia or among the planes of the abdominal muscles. The smaller the abscess the less serious the inevitable operation, and the more amenable the cavity to successful treatment.

The method of evacuating psoas abscess, which he has adopted in a large number of cases, and which he recommends, is by a free anterior as well as posterior opening and by then washing and draining the cavity right through. The first opening is made close above the outer end of Poupart's ligament, using the scalpel until about an inch of the length of the fibres of the aponeurosis of the external oblique has been exposed. The fleshy attachment of the internal oblique and transversalis are then scratched through, and a director thrust into the swelling, keeping well below the level of the peritoneum. Pus escapes, and the opening is enlarged by the dressing forceps and the finger. A stiff probe is then passed through the abscess cavity and made to project beneath the skin on the outer side of the erector spinæ. With this as a guide, a counter-opening is made in the loin. The cavity is then flushed perfectly clean with a warm antiseptic solution, and a drainage-tube of the size of a penholder is laid through the abscess-cavity for a few days, and is afterwards replaced by a silk thread. The parts are covered with large pads of wood-wool and finely picked oakum in gauze

bags. These are kept in position by a towel arranged as a binder, which, for the sake of compression, is tightly drawn and fixed with safety pins. Next day the cavity is again washed out—under chloroform, if necessary, —the wounds being dressed as before. After this, the less the abscess is interfered with the better; if the temperature do not rise, and the discharge do not soak through, the dressings may be left on for three or four days, or longer. From the first day the discharge becomes thin and watery; suppuration in the ordinary sense of the word is at an end, and the cavity steadily contracts into a narrow passage.

If the abscess be so small that the surgeon does not feel inclined to attack it from the front, he may readily work down on it above the crest of the ilium, on the outer side of the erector spinæ muscle. The scalpel is needed only for the skin incision, the rest of the operation being performed with ease and safety by the use of a steel director and the dressing forceps.

CONSISTENT FOLLY.

There has recently been an interesting and instructive episode in the history of what is known in Philadelphia as the Women's Homœopathic Hospital. The circumstances were these: Certain of the medical staff were found to be departing in their practice from the principles of homœopathy, and were notified that this course was not agreeable to the founders and supporters of the hospital. As this notification was not heeded some further remonstrance was made by the managers of the hospital, and eight of the staff—all women—resigned. When the matter became public, the resigning physicians explained that they did not care to remain longer connected with a hospital where lay persons interfere with the work of physicians, and assume to direct what shall be prescribed. The managers had made a rule that "no medicines, except strictly homœopathic potentized remedies, should be used in any department of the hospital."

On the part of the managers it is claimed that no other course is open to them than that which they have pursued, and they deny that they have dictated to the doctors. They say the difficulty with the women physicians who have resigned is because of the use of crude and unproved drugs in the hospital, in violation of positive rules and of the principles of pure homœopathy.

The money with which the hospital has been built was given with the express condition that the institution was to be conducted in accordance with the principles of pure homœopathy, and the use of crude drugs and alcoholic liquors is directly opposed to those principles.

In this small controversy a very important principle is involved, and we congratulate the managers of the Women's Homœopathic Hospital upon the firmness with which they have insisted that their institution shall not be used as a means of deception, pretending to be homœopathic and being actually eclectic. The physicians who have resigned may know more about the use of drugs than the managers; but the latter seem to be better judges of consistency. The outcome, however, must be to show the folly and danger of the exclusive doctrines of Hahnemann.

SEXUAL STARVATION.

The interesting lecture of Dr. Lydston, which opens this number of the REPORTER, contains, besides other useful matter, such sensible and clear suggestions in regard to the management of certain troubles caused by prolonged celibacy, that we think it worth while to direct the attention of our readers more especially to them; and to add our own endorsement of them. There is no problem of our modern civilization which it is harder to discuss in a manner which shall be at the same time thorough and pure; and so many, who have attempted the discussion, have, from choice or necessity, sacrificed purity to the attempt at thoroughness, that we are glad to be able to present a study of the subject, which, so far as it goes, does not offend the strictest idea of propriety.

NOTES AND COMMENTS.

The American Medical Association and Journal.

The *Journal of the American Medical Association*, for May 7, 1887, contains information of great interest to members of the Association, concerning the programme of work, both in general session and in the sections at the coming meeting of the Association. The programme is as yet incomplete, and it is desirable that further reports of papers and contributors should be forwarded to the Chairman of the Committee of Arrangements as early as possible. The indications thus far point to a large meeting, and one of the most important that have been held in many years. The promised liberal reduction in railroad and hotel charges,

the central position of the place of meeting, and its easy access from all directions, are favorable for a large gathering of representatives from every section of our country. And they will certainly receive a cordial welcome from the profession and citizens of Chicago.

The Editor of *The Journal* reports that much progress has been made during the four years since the first number was issued. At that date, 1883, and for the preceding five years, the average annual receipts of the treasurer indicated less than 1,000 members regularly paying the annual membership dues, while since that period the number has increased more than three-fold, and with the receipts from subscribers and advertisers, has so increased the income that, instead of $5,000 as in 1883, it will reach not less than $20,000. This is a result upon which we congratulate the Association and its *Journal.*

Fœtal Therapeutics.

In an original article with this title in the *American Lancet* of May, 1887, Dr. T. C Smith presents the following conclusions:

1. That remedies administered to the pregnant woman find their way by osmosis to the fœtal circulation, and therefore will influence the fœtus quite promptly.

2. It is probable that the influence will be proportionate to the dose taken by the pregnant woman, and we should therefore exercise care in all remedies given to such women.

3. In pregnant women with decided syphilitic taint, the continued or persevering use of proper remedies tends decidedly to preserve the viability of the fœtus to the end of the puerperal term, and to prepare its blood and tissues to be brought forth in a purer state than it possibly could be without such treatment.

4. Any recognized dyscrasia of the mother which is likely to destroy the fœtus may often be met and fœtal viability secured to the end of term.

5. In cases of fatty degeneration of the placenta, where the placental respiration is sufficient to maintain fœtal life to the end of the term, we may hope by the use of proper remedies given to the mother to increase the respiratory capacity of the placenta, and thus retain fœtal viability to the end of term.

6. Violent and threatening movements of the fœtus may be controlled by giving proper remedies to the pregnant woman.

7. The administration of any powerful agent to the mother may lead to the death of the fœtus, if too largely given.

8. The fœtus may be affected by contagion in the pregnant woman's system, when she herself does not contract the contagious disease; as in the case of Mauriceau, as given by Leishman.

9. The fœtus is often destroyed by constitutional and contagious diseases which attack the pregnant woman, or to which she has been exposed; as in small-pox, scarlatina, rubeola, etc.

10. "Occasionally the child, when thus affected, passes safely, while in utero, through a full course of small-pox, and is at length born with the pits of the disease alone remaining. I vaccinated repeatedly a person born under these circumstances, and always unsuccessfully." (Sir J. Y. Simpson's Obstetrical Works, vol. ii., p. 360.)

11. "This affords presumptive proof that variolous, and perhaps other contagious febrile matters, affect the body by first entering the vascular system." (Loc. cit.)

12. "The morbid matter can pass thus from the mother to the fœtus only through the medium of the circulation, for there is no communication by the nervous system between the economy of the mother and that of the fœtus." (Loc. cit.)

13. If our premises are true and our clinical experiences reliable, then, surely, we have great reason given us to see how and why we should look after the treatment of the unborn fœtus, when necessary, as well as the infant that sports joyfully on its mother's breast. The safety of both mother and fœtus may often demand this at our hands.

Iodized Starch as an Antiseptic.

England describes his preparation and use of this substance as follows in the *American Journal of Pharmacy*, for April, 1887:

Apropos of the subject of antiseptics, the author was led some months ago to advocate the use of *iodized starch* as an addition to our rapidly growing list of these compounds. Reasoning that the antiseptic activity of iodoform and bismuth subiodide must depend, in part or wholly, upon the iodine freed in their decomposition, in contact with decomposing putrescent organic matter, it was thought that if an iodized compound, readily decomposable, was subjected to the same conditions, that it would induce the same healthful process in the latter case as well as in the former. Full experience has demonstrated the value of the theory in this instance, and iodized starch is now used daily in our hos-

pital practice, and recognized as a valuable adjunct in certain forms of antiseptic treatment. It is applied in the same manner as other antiseptics, namely: first washing out the wound with pure water, and drying out as far as practicable, then thoroughly dusting in with iodized starch and covering the wound, even beyond its outer edges. The applications are generally made in the morning and evening.

On the removal of the dressings the absorption of the iodine is most strikingly shown. Whereas in the central parts of the wound, where the exuding pus or matter has come in contact with the bluish-black powder, the same has become wholly decolorized, and shows the white color of the starch, yet, around the outer limits of the dressing, where no excretive matter has exuded, the bluish-black color remains unaffected.

Comparative trials with iodoform, subiodide of bismuth, and iodized starch have demonstrated that the latter possesses valuable antiseptic qualities as a dressing; and though it may not be superior to the first two named, yet, at the same time, it has occasionally succeeded where they have given unsatisfactory results.

In its preparation the pharmacopœial method, given under "Amylum Iodatum," has been followed, namely, the trituration of 5 parts of iodine with a small quantity of distilled water, and the gradual addition of 95 parts of powdered starch, until the compound has assumed a uniform, bluish-black color. Then dry at a temperature not exceeding 40° C. (104° F.), powder and bottle or box.

Pediculosis Capitis.

In a clinical lecture at the Children's Hospital, Philadelphia, reported in the *Archive of Pediatrics* for April, 1886, Dr. A. V. Meigs said: This girl, about ten years of age, is brought to us by her mother, with the statement that there is an eruption upon the head which began when the child was four years old. She states that this eruption under treatment has improved several times, but for the last two years it has been much worse. In other respects the child is perfectly healthy. An examination of the head at once reveals the presence of pediculosis. The hair is filled with lice, the pediculus capitis, and it is covered with nits. The secondary result of this source of irritation is eczema. In such conditions I have never been able to cure the disease without cutting off the hair. Although the lice are readily destroyed, the nits cannot be removed without great difficulty, and unless the hair is cut the parasites will be as numerous as ever in a few days. The only way to accomplish a cure is to cut off the hair, and then in a few days the trouble can be relieved. Pediculosis of the head is much more difficult to cure than the same affection of the body. After the hair is cut off, the head should be thoroughly washed with a solution of corrosive sublimate in alcohol, one grain to the ounce. Although in the irritated condition of the scalp this may cause some stinging, yet it will do no harm to make one application, or possibly two. The case should then be treated as one of ordinary eczema, by the application possibly of oxide of zinc ointment. I am frequently asked if there is not danger from the use of this preparation of mercury. I have never seen the slightest constitutional effect from the use of corrosive sublimate about the head or body in persons suffering from pediculosis. This is also very efficacious in the treatment of pediculosis pubis. Here two or three applications will usually cure the trouble.

American Archæology.

Dr. Daniel G. Brinton delivered the last of an interesting and well attended series of lectures on American Archæology at the University of Pennsylvania, on Friday afternoon, the 6th instant. Speaking of "Arts and Sciences," he said: The early Americans were representatives of the stone age in most cases, although a few possessed the knowledge of metals. They were particularly clever stone workers, and the samples of their craftsmanship show them well versed in the arts of the potter. In clay moulding they were also skillful. The textile arts were practiced, such as cotton and wool spinning and weaving. Cotton was extensively raised in Mexico and Yucatan, and two species of goats were acclimatized to Peru for the sake of their wool. As to their architectural methods, the lecturer said they were not familiar with the plumb line, but adjusted their building materials merely by the eye. They were familiar with two kinds of arches, also square and rounded pillars. The lecturer called attention to the love of music that prevailed, and the astronomical progress that our American forerunners seem to have reached. They learned the length of the solar year, and in their leap years made provision for the necessary "extra day." They pursued thorough agriculturical methods, and practiced fertilization and irrigation.

Dr. Brinton further referred to the extensive commerce which prevailed among the American races, and closed with a mention of their love for sports and out-door games. Early American art in general the lecturer criticised as much below that of ancient Egypt and Assyria in point of appreciation of the beautiful.

Antifebrin in the Treatment of Phthisis.

In an interesting paper in *The Medical Record* for April 16, 1887, Dr. C. H. Cauldwell reported his experience with antefebrin in the treatment of consumption. His conclusions concerning its use are as follows:

1. Antifebrin is the best drug with which to control the chill and fever of phthisis. With it we can at once check these depressing symptoms.

2. It does not produce the unpleasant effects of quinine, salicylic acid, antipyrine, thallin or resorcin.

3. Chills, collapse, or semi-intoxication are not caused by it.

4. In many patients it induces sweating.

5. It diminishes the frequency of the pulse, and usually strengthens the heart's action.

6. Occasionally it produces cyanosis. This happened but twice in thirty cases.

7. It does not interfere with digestion, but on the contrary increases the appetite.

8. Even when the stomach is in an irritable condition, it can be retained.

9. It increases the secretion of urine in the majority of cases.

10. It tends to quiet the nervous system and produce a feeling of "well being" in the patients.

Tea Poisoning.

Dr. Moton, in the *Medical Times*, in 1879, drew attention to the effect of tea on tea-tasters, and from time to time the use of the beverage has drawn forth opinions from both friend and foe—the most startling of the adverse opinions being Dr. J. R. Wolfe's paper on the softening of the vitreous humor from tea drinking—and the following which we copy from a foreign contemporary is enough to alarm even a Johnsonian tea drinker: "Russian tea merchants who, when present on the Chinese frontier for buying the article, are obliged to taste from 150 to 200 specimens of strong tea-infusions daily, do not swallow the infusion, but nevertheless a slow intoxication appears in them. The symptoms are loss of appetite, constipation alternating in diarrhœa, failure of general nutrition, periodical epigastric pains, enlargement of the liver with subsequent atrophic cirrhosis, and dryness and sallowness of the skin, hypochondriacal frame of mind, marked failure of memory, of sight (weakness of visual acuity, sometimes diplopia), and of taste and smell.

Electrical Aids in the Treatment of Insomnia.

G. Betton Massey, M. D., writes as follows in the *Medical News* of May 7, 1886: Simple anodic faradization of the occiput is frequently attended with most gratifying results. In making this application the cathode should be placed in the position least likely to give rise to sensation (on the heel is preferable, but *not* on the thin skin of the instep), both poles being well moistened. The current is increased at once from the initial weakness to a strength that is distinctly felt at the anode, and is not increased further, notwithstanding the rapid fading of the sensation as the nerve ends become tolerant of the stimulus, for a gradually increasing faradic current is anything but sedative. The full effect of this application requires that the note emitted by the hammer of the interrupter shall be clear and free from quavers due to irregular vibrations.

Action of Saline Purgatives.

M. G. Leubuscher offers the following conclusion, in regard to the action of saline purgatives, after a series of experimental researches in this line:

"1. That an exaggeration of the peristaltic movement of the intestine only plays a secondary part in the action of saline purgatives.

"2. In whatever manner saline purgatives may be introduced into the intestine, the intestine becomes the site of a great secretion of liquid, which is the principal cause of the purgative action.

"3. It is impossible to claim for saline purgatives that they act as a barrier to reabsorption.

"4. Saline purgatives introduced into the circulation in sufficient quantity produce constipation."—*Edinburgh Medical Journal.*

The Average Income of the Family Doctor.

The average income of the family doctor in England, according to estimates made by Dr. E. Paget Thurstan in the *Lancet*, is £625 or $3,125. Deducting the average working expenses and the interest on capital

sunk, the average net income is estimated at $1,775. If there be included all the physicians having only salaries as assistants, etc., or having no practice, the average net income is placed at about $1,000.

An average gross income of $3,225 is very much beyond that earned by American physicians, if we include the younger men who are still striving to establish a practice. This is the natural result of the fact that we have twice as many doctors proportionately as there are in England. We have to divide the fees.

Quinine Amaurosis.

Dr. Edward Browne, of London, has lately collected eighteen cases of quinine amaurosis. The symptoms were blindness and deafness of a marked character. The deafness was brief in duration, and the recovery rapid. The onset of the amaurosis was sudden, and more complete than was known in any other recoverable condition. It resembled the dense darkness of atrophy.

Hyperemia of the retina is a very common malady these days. It may be a transient affection depending on overwork of the eye, or upon a deranged state of the stomach. In these circumstances the congestion passes away so rapidly that it is not likely to attract attention from either the surgeon or the patient.—*Dr. Benj. J. Baldwin, in the Alabama Medical and Surgical Journal.*

Important Metallurgical Discoveries of a Physician.

Dr. C. C. Carroll, of Meadville, Pa., after years of experimenting, has discovered a method by which aluminum can be cast, soldered, and welded. It is claimed by metallurgists and artisans that this is a very valuable invention, since it insures the use of aluminum for many purposes on account of its extreme lightness, strength and non-oxidation by exposure. It is already successfully employed in the manufacture of the dental plates, for which it is apparently admirably adapted. In the course of his experimenting, Dr. Carroll believes he has also discovered the law governing the disintegration of iron stringers employed in the construction of railroad bridges.

New Method of Employing Electricity in Neuralgia.

Dr. Adamkiewicz describes in the Polish journal *Przelad Lekarski* an exceedingly effective way of applying electricity for the relief of neuralgia of various kinds. The apparatus he uses is a constant-current battery, the cathode being a concave metal plate lined with electrical carbon, which is saturated with chloroform. This is then applied over the painful spot, and a current, weak at first, but gradually increasing in strength, passed. One or two applications of this kind were found, says the author, sufficient entirely to relieve the severest cases.

Decadence of Homœopathy.

We have the authority of the *Medical Record* that a prominent publisher of a regular medical book sells more books proportionately to the homœopaths than to regular physicians. The fact is but an addition to the accumulating evidence of decadence of homœopathy as a system of therapeutics. The number of consistent homœopaths whom the public regard as such is rapidly growing beautifully smaller, and the time is not far distant when only cranks and men who sail under the name as the pirate sails under the flag of an honest merchantman will fly the legend homœopathy on their shingles.—*The Medical Age.*

Hydrobromate of Quinine.

Hydrobromate of quinine is the subject of a long article in the *St. Petersb. Med. Wochenschr.*, by Dr. Maximo Noviteh, who has for some time past been engaged in studying the relative merits of the different salts of quinine.

He considers the di-hydrobromate the most useful salt. Its advantages are greater solubility, no tendency to produce irritation of the skin when used hypodermically, its causing less cerebral annoyance. hence Jaccoud employs it exclusively in typhus. Steinitz and Professor Rosenthal recommend it for whooping-cough, hysteria, nervous vomiting, and the pains of ataxy.

Solanine.

The alkaloid extracted from *Solanum nigrum* and also from the fruit of the potato plant, is being employed to relieve acute pain and as a narcotic in the place of morphine. It is said that its administration in large doses does not occasion the nausea and vomiting which occurs frequently from the use of this latter. The therapeutic dose is from ¾ gr. to 4 grains, and 7½ grs. have been given without any unpleasant effects. Solanine and its hydrochlorate are prepared

at the well-known laboratory of M. Mialhe, Rue Favart. The price varies from 6f. to 10f. the gramme.

Pomade for Cutaneous Disorders During Pregnancy.

Monin, in *L'Union Médicale*, of March 29, 1887, gives the following formula:

℞. Zinc. oxid. pulv.		gr. iij.
Hydrarg. ammoniat.		gr. iss.
Ol. theobromi,		
Ol. ricini,	āā	ʒijss.
Ol. rosæ,		gtt. x.

This may be applied to the face morning and night.

Peroxide of Hydrogen

Is recommended by Dr. B. W. Richardson, in the *Asclepiad*, as a remedy of some value in whooping cough. He believes it to act like dilute nitric acid, subduing the spasmodic paroxysm, checking secretion, and shortening duration of the disease. It is, however, more effective than this acid. The formula employed is — hydrogen peroxide ʒvj., glycerine f̄ʒiv., water to f̄ʒiij. Of this mixture half a fluid ounce is given in a wineglassful of water five or six times a day.

Pure Chromic Acid.

A new form of chromic acid, prepared by Merck, and alleged to be absolutely free from sulphuric acid, and hence very slowly deliquescent in dry air, is now procurable. The acid is in the form of small dry red crystals, readily soluble in water and in alcohol. It is said that the acid in this form does not spread over the surrounding tissue, and is therefore better suited for use in places where it would be dangerous to employ the ordinary acid.

Arsenical Eruptions.

Dr. P. A. Moroon (*La France Médicale*, 11th January) has observed the following variety of cutaneous eruptions from the use of arsenic: Erythema, papules, urticaria, vesicles, pustules, ulceration, skin bronzing. In each case the discontinuance of the drug caused the disappearance of the rash.

For Blistered Feet.

Salicylic suet is used in the German army as a remedy for foot-sores, instead of the salicylic powder formerly employed. It is composed of two parts of pure salicylic acid and ninety-eight parts of the best mutton suet.

Bergeon's Method in Asthma.

At the meeting of the Philadelphia County Medical Society on May 11th, Dr. S. Solis-Cohen read a paper with this title, the full text of which we shall present in an early issue of the Reporter.

Correspondence.

The Use of Forceps.

Eds. Med. and Surg. Reporter:

I see in the Reporter, as well as a number of other journals that come to my office, that the forceps are just now a subject of vigorous discussion, pro and con.

Dr. Mitchell, of Pennsylvania, seems to entertain a very decided distrust of, if not repugnance, to them. It is true, the doctor does not relegate them to absolute oblivion, but the faint praise bestowed upon them is equivalent to their condemnation. The literal butchering depicted, and the bloody scenes described as sequences of the use of the forceps, if "taken at their word," would certainly deter a young doctor from their use, even if he was so fortunate as to escape the "curdling of his blood" by their perusal.

Beneath this remarkable and phenomenally successful obstetrical career of Dr. Mitchell, of a life-time practice of obstetrics without the use of the forceps, lies a criticism and condemnation of all others who have felt the necessity of the aid of the forceps. If Dr. A can practice obstetrics a life-time without their use, Dr. B is unskillful, careless, or impulsive if he fails to do the same thing. The natural inference drawn from Dr. M.'s articles is that all of the torn perineums are the result of the forceps—when the truth is that the perineums of a large number of primiparæ are torn to a less or greater degree, whether the forceps have been used or the child delivered by the unaided efforts of the woman. When a solid, almost unyielding mass, four and a half to five and a half inches in diameter, is forced through an avenue or opening that is frequently not more (in its natural state) than one inch in diameter, a certain per cent. of the openings will be torn in spite of the most skillful management.

There is another side to this question: how many mothers have lost their lives or suffered from the many casualties incident to prolonged labor, such as bladder and rectal fistula, sloughing of the soft tissue of pelvis, nervous exhaustion, loss of blood, etc., etc., because of the failure to use the forceps?

How many children have been stillborn from the same cause? Your humble servant has been for a number of years engaged in "chewing the cud of bitter reflection" on account of the loss of the lives of two "confiding women" who had entrusted themselves to his care, and died *because the forceps were not used.* The first occurred when he was a young man, when torn perineum and many other imaginary ills as the result of the forceps deterred him from their use; the second was lost by being hampered by a consultant who had never used forceps, and was opposed to their use by others. I have been in practice for more than a quarter of a century, and I would advise my younger brethren to always and upon every occasion take the risk of tearing the perineum rather than lose the life of the woman. Take all risks short of that of death to her.

I must confess that I use the forceps, and as I grow older and *more cautious* I use them more frequently. I have never had an "irreparable injury" follow their use in my hands. In two cases "great gaping wounds staring me in the face," occurred where the forceps had not been used, and were not "monuments to my lack of skill and judgment," either.

On April 6, 1886, I attended a primipara through an apparently natural labor of eight hours' duration—the child weighing nine pounds. Upon the delivery of the afterbirth I found the perineum intact, but, starting just within its border on the left side, and running upward and a little to the left, was an irregular gaping tear, whose presence might have set me to "cud chewing" *if I had used the forceps during delivery.* But fortunately for the cud and me also, they had not been used. If they had been used this would have been a legitimate forceps "butchery," if it had been reported—the wound was full three inches in length.

Now with all deference to the judgment of other practitioners, I make the radical statement that the forceps in skillful hands, and used when indicated, are one of the greatest blessings to suffering woman.

There is no excuse or justification for their unskillful use, unless it be found in the teaching of such as oppose and condemn them, thereby preventing our young men from the careful study of their application and use.

The innumerable opportunities and facilities now open and accessible to all students of medicine, enabling them to become proficient in their profession—the almost perfect forceps that are within the easy reach of all —and the small amount of danger in their use, seem to me a justification to the physician who resorts to them to reduce the time of the awful pangs and agonies attendant upon the labors of some women. A woman of this class, who has once been delivered by the forceps in competent hands, will beg piteously for their use, if called upon to pass again through the ordeal. There are many contingencies requiring the use of the forceps—imminent danger of laceration of the womb, alarming hemorrhage, danger of sloughing from long-continued pressure upon the soft parts, exquisite pain and spasm of the thighs and calves of legs from head pressure upon pelvic nerves, rapid exhaustion of the mother, prolapse of the cord, endangering the life of the child, retention of the child's head after the body is delivered—these, and many others, not only justify, but imperatively demand the use of the forceps when the parts are in a condition permitting their use.

J. B. Hatton, M. D.

Red Oak, Iowa.

Midwifery in the Country.

Eds. Med. and Surg. Reporter:

Since reading the article by Dr. Mitchell in your issue of January 22, I have taken the trouble to look up the number of actual cases of confinement that I have attended, to make sure that in approximating in my previous communication I had not seriously erred. I find that I shall be obliged to apologize for misstating; the exact number is three hundred and ninety-eight; I take back two from my former estimated labors, and ask pardon. Perhaps my experience has been a little greater in the given number of years, from the fact that I am alone in that line of practice in a country quite thickly populated, and no doctor nearer than six miles who attends confinements at all. Success in the practice of obstetrics is as necessary to build up a good business as a physician, as good sermons are to make a popular preacher; and while Dr. M.'s unusual success, as far as mothers is concerned, is excellent, having lost only one, I am happy to say that as yet I have not lost *one.* It doubtless is not due to particular excellence in my plan of procedure—rather to a fortunate class of cases. I always anxiously wait for a period of two or three days to elapse after completion of labor before feeling relieved in mind. I do not believe that forceps skillfully used tear any more perineums than we find in natural deliveries without their use. I have seen but one torn, and that

occurred in my practice six years ago, when so far away from my instruments that I could not get them. Does a torn perineum necessarily involve a lifetime of misery? Surely not. Surgery of these parts is productive of excellent results. What prevents the torn perineum healing when properly stitched, and when healed where does the misery come in? It really seems as though "the cud of bitter reflection" might be more appropriately "chewed" when thinking of those cases in which, the physician having "possessed his soul in patience" until exhausted nature was unable to properly perform her duty after delivery, hemorrhage takes place, and, if not death, a slow tedious recovery follows. Unless some abnormality exists, it is no more necessary to tear with forceps than to cut the lips when extracting teeth. Dr. Mitchell cannot believe any beneficial result could follow the method of treating rigid os proposed by me. If he will try it he will do no harm, and if no good follows then he can *intelligently* differ with me. Chloroform should not be given to complete anæsthesia in ordinary cases, and if not used beyond the point required to give relief, it does *not* retard labor at all. When the pains are hurried, giving the woman no rest, and only lasting long enough to barely engage the head and then giving up, it tends to diminish the frequency but increases the time occupied by the pains, thereby *hastening* the final result. I thank the Doctor for criticising my article so sharply, as it served to make me look up authorities on the subject which have strengthened me in my position.

H. L. Manchester.

Pawlet, Rutland Co., Vt.

News and Miscellany.

Aid for the Veterinary School.

The appropriation of $100,000 for the Veterinary Department of the University comes before the House for final passage this week. There should be no question about this appropriation in a great agricultural State like Pennsylvania. This country loses millions yearly through animal diseases, whose origin, cure, and prevention will never be discovered except by a college like that which this appropriation will keep open, for without aid it will be impossible to maintain this department of the University on its present basis.

Letting alone other states, Pennsylvania farmers lost by disease last year, as official reports show, 35,212 milch cattle, 35,684 sheep, and 44,136 swine. This is a yearly loss—1886 returning losses one-half those of 1885—which is from two to three times as large as it would be if veterinary science were properly studied, and a very small percentage of reduction in this loss would in a few years repay the proposed appropriation a hundred-fold. If any other trade but farming were losing from 3 to 10 per cent. from causes which inquiry would remove, the Legislature would be besieged to pay for the education of experts in the hope of securing relief. We advise legislators not to neglect the farmer.

The school has thus far been most successful in its work, and its curriculum is longer and more rigorous than that required in any school of human medicine in the country. All that is asked now is buildings and the accommodations needed to carry on a growing institution. This the school should have. It is a small insurance for a State which has millions of dollars invested in domestic animals, and loses hundreds of thousands of dollars yearly from preventable diseases among them.

A Question of Medical Practice Discussed by the Supreme Court.

The Supreme Court of Pennsylvania heard argument on the fourth instant, in a case appealed from the Court of Quarter Sessions of Lebanon county.

Dr. John Ege was a regular practicing physician, residing in Reading, in Berks county, and was duly registered in that county in August, 1883, under the act of 1881. He also registered under the same Act on the the 18th of May, 1885, in Lebanon county, but before this registry he had a number of patients in Lebanon county who visited and consulted him at his office in Reading, and for their convenience he occasionally visited Lebanon, giving notice of his coming, the time and place at which he could be seen and consulted, and styling himself in the newspapers as "Dr. John Ege, of No. 1002 Penn street, Reading." When he came to Lebanon he was visited and consulted by his patients at the address given in the newspaper notice, and was also visited by new patients, for whom he prescribed and was paid by them for his services. He was arrested, and was prosecuted by a committee of physicians for a violation of the Act of 1881 in practicing in Lebanon county when not registered there. A verdict of guilty was

taken by the Court. The Doctor appealed to the Supreme Court, where the case was argued. Decision was reserved.

Vaccinated Indians.

The United States sanitary inspector at Yuma, Arizona, in his report for the week ended April 16, 1887, states that the Yumas and other tribes of Indians in that vicinity have been thoroughly vaccinated and are well protected against small-pox. For the past two months they have been suffering from a severe epidemic of measles; 180 cases and 60 deaths have been reported up to April 16. They have no physician, and their vicious habits of destroying their property for the benefit of their dead, left them early in a destitute condition, without food, clothing or houses; and the great percentage of mortality may be accounted for by complications arising from exposure and want of proper food.

Japanese Cod Liver Oil.

The Japanese do not appear to be lacking in commercial enterprise. According to a note in *Nature*, the Japanese government has despatched an official of the Ministry of Commerce to Norway in order to study the cod fisheries, and the preparation of cod liver oil in that country. In the north of Japan large numbers of cod-fish appear at certain seasons of the year, and it is intended to develop this industry. Japanese cod liver oil is already known in the London market, but, doubtless, the inquiry now being made will lead to the preparation of a superior article in Japan.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS.

U. S. Marine Hospital, for the week ended May 7, 1887:

Wyman, Walter, surgeon. Detailed as chairman Board for physical examination of candidates for appointment as cadet, Revenue Marine Service, May 6, 1887.

Mead, F. W., assistant surgeon. Detailed as recorder Board for physical examination of candidates for appointment as cadet, Revenue Marine Service, May 6, 1887.

"Bill."

Physicians' prescriptions were originally called "bills." Sir Thomas More (1829) writes: "After the billes made by the greate physicion God, prescrybynge the medicines himselfe"; and Butler, in "Hudibras" (1663), says, "Like him that took the Doctor's Bill, And swallow'd it instead o' th' pill."

A Clairvoyant Sentenced.

In Philadelphia the County Medical Society is keeping irregular practitioners stirred up by instituting legal proceedings against a variety of breakers of the law for the registration of physicians. The last case is that of a man who called himself Dr. Charles Bond, an alleged clairvoyant, who was recently sentenced to one year's imprisonment for practicing without being registered.

Swiss Delegates to the Congress.

We learn that the Swiss Confederation has appointed Professor Theodor Rocher, of Berne, Switzerland, and Dr. Henry A. Banga, resident in Chicago, U. S. A., as delegates to the International Medical Congress, to be held in Washington, September 5, 1887.

The West Virginia State Medical Society Will hold its twentieth annual session at White Sulphur Springs, W. Va., July 13, 14 and 15, 1887. The Secretary is J. L. Fullerton, M. D., of Charleston, W. Va.

Items.

—Dr. Richard J. Levis has returned from his trip to Europe.

—St. Paul, Minn., reports a death-rate for 1886 of only 12 per 1,000.

—Dr. S. P. Duffield, of Dearborn, Mich., has been elected Health Officer of Detroit, to succeed Dr. Wight.

—Dr. O. W. Wight, who has been Health Officer of Detroit, Mich., for several years, sails on May 18 for Europe.

—The N. Y. Homœopathic Life Insurance Company has passed into the hands of a receiver.—*New York Medical Times, May*, 1887.

—The American Neurological Association holds its thirteenth annual meeting at Long Branch, N. J., on July 20th, 21st and 22d.

—Dr. E. C. Spitzka, of New York city, has accepted the vice-presidency of the Section of Anatomy of the Ninth International Medical Congress.

—The Penn Mutual Life Insurance Company of Philadelphia has appointed Drs. Clara Marshall and Anna Broomall examiners for a special class of risks among women.

—The Boylston Prize of the Boylston Medical Society of Harvard University has been awarded to Mr. Charles L. Scudder for an essay on "Congenital Talipes Equino-Varus."

—The State Medical Society of Wisconsin will hold its forty-first annual session at Oshkosh, commencing on Tuesday, May 3d, at 8 p. m., under the presidency of Dr. S. C. Johnson, of Hudson.

—At the annual meeting of the Chicago Medical Society, held April 4th, Dr. Wm. T. Belfield was elected President; Dr. J. H. Etheridge, First Vice-President; Dr. Sarah H. Stevenson, Second Vice-President; Dr. Frank Billings, Secretary; and Dr. H. N. Moyer, Treasurer.

—The particular office of flies appears to be the consumption of those dead minute animals whose decaying myriads would otherwise poison the air. It was a remark of Linnæus that three flies would consume a dead horse sooner than a lion could. He, of course, included the families of the three flies.

—A householder in Jersey City has brought suit to recover $20,000 damages against City Health Inspector Benjamin and his assistants, for dumping night-soil against the rear fence of his premises. He claims that five of his children died within three days from disease contracted in consequence thereof.

—Dr. Neyron, professor of anatomy in Notre Dame University, Indiana, is the Nestor of physicians in this country. He is ninety-four years of age, and was a surgeon in Napoleon's army during the Russian campaign and at Waterloo. He is still able to conduct his classes, and few men of seventy, it is said, are so strong and active.

—Our English confrères are chafing under the carriage-tax, which in spite of efforts to secure its reduction, remains at two guineas, in some cases, amounting, it is said, to fifteen per cent. of the cost of a vehicle. To the country practitioners especially, the burden is very heavy, and prevents them from keeping a close carriage for rainy weather, and a cheaper open vehicle for fine days.—*Boston Medical and Surgical Journal.*

—The ninth annual meeting of the American Climatological Society will be held at Baltimore, on Tuesday and Wednesday, May 31st and June 1st, and we understand that interesting papers have been promised by Drs. Loomis, Trudeau, Westbrook, Shattuck, Donaldson, Musser, Curtin, and Reed, all on phthisis in one or other of its phases. Drs. Rice and Peale will make reports on mineral springs, and Dr. Linn on some health resorts.

—The *Therapeutic Gazette* calls attention to massage as an employment especially suited to the capabilities of the blind, in whom the tactile sense is so strongly developed, and remarks that, in Japan, massage has been for a long period of time practiced by blind men, who go about the streets with a flageolet, to call attention to themselves and their occupation. It adds the hint that superintendents of blind asylums will do well to consider this as a possible avenue for labor for their pupils.

OBITUARY NOTICES.

Elliston R. Bateman, M. D.

Dr. Bateman was born in the village of Cedarville, N. J., where he died. He was the son of Dr. Robt. Bateman, deceased; and the grandson of Dr. Eli E. Bateman, deceased. He was carefully educated at Blair Hall and at Princeton college. He received his medical education under the tutelage of his grandfather; and was graduated from the Medical Department of the University of Pennsylvania in the spring of 1882. He acquired considerable practice, and was held in high esteem by many families who employed him. Never having been robust, he began, about two years since, to show symptoms of the disease which caused his death—phthisis pulmonalis. His life was unostentatious and unobtrusive; and in the church, of which he early became a member, he was rather a hearer than an aggressive worker. He leaves a wife, but no issue—his two children having died in infancy. His remains find rest in the cemetery attached to the first Presbyterian church, of which he was a member. His age was about 27 years.

Elliott Richardson, M. D.

It is our painful duty to announce the death, in Philadelphia, on May 9th, of Dr. Elliott Richardson, who was best known in connection with the practice of obstetrics and gynæcology. He was a most careful, conscientious and competent practitioner, modest and unassuming, and a man of true worth. He had many warm friends, who will miss his presence in social gatherings and in the meetings of the medical societies to which he belonged. He had the distinction of having performed the first successful Porro operation in this country.

TO PHYSICIANS.

Your patients doubtless frequently call upon you to advise them regarding imperfect sight. Upon application, we will send our directions for measurement, the simplicity of which requires no special optical knowledge.

SOLUBLE
PILLS AND GRANULES

UNEQUALLED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by
ROBERT SHOEMAKER & CO.

SOLUTION FERROUS MALATE.
FOUR GRAINS TO FLUID DRACHM

(Amer. Phar. M'f'g Co.)

DOSE.—30 to 60 drops, four times a day.

Exerts the full therapeutic influence of iron, while it does not constipate, nauseate, produce headache, or cause any of the other unpleasant effects resulting from the use of ordinary forms of iron.

Solution Ferrous Malate will combine perfectly with Acid. Sulph. Aromat. and in this form really represents the therapeutic value of the Tinc. Chloride Iron, rid of all its objectionable features.

The late Prof. Gross, who at one time had occasion to use it in his own case, said, "I am highly pleased with it. I obtained all the benefit from it that I can get from Iron."

Ferrous Malate, Gentian and Cinchona.

(Amer. Phar. M'f'g Co.)

DOSE.—Dessert to table spoonful three times a day.

This is said by Physicians to be a happy combination, embodying as it does, a blood tonic, a stomachic and an anti-malarial, as well as a beneficial conjoint influence that neither Iron, Gentian or Cinchona alone is known to possess.

JOHN C. BAKER & CO, Wholesale Agents,
815 Filbert Street, Philadelphia.

Platt's Chlorides
THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.
INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant. Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

Lecture.

LEAD ENCEPHALOPATHY—CHRONIC MYOCARDITIS.

A CLINICAL LECTURE DELIVERED AT THE PHILADELPHIA HOSPITAL.

BY J. H. MUSSER, M. D.,

Physician to the Hospital.

Reported by William H. Morrison, M. D.

Gentlemen: The first case for study is a rare and interesting one. The patient is now in a much better condition than he was when he first came under observation. He was admitted about two weeks ago, and at that time appeared to be intoxicated, or at least suffering from the effects of alcoholism, and he was placed in the wards set aside for the treatment of such conditions. It was soon found that a more serious affection than alcoholism was present. When first seen, the patient was in a condition of semi-coma. He could be aroused from the deep stupor by the application of irritants to the nostrils, by loud calling, and also by placing food or water in his mouth. He would at once relapse, however. He continued in this state until a short time ago. Previous to admission, the patient had been sick and had been treated in another institution for a phase of the disease which I shall hereafter mention. I may say, however, that so far as we can determine, there had been no cerebral symptoms.

The patient is forty-one years of age, a painter by occupation. He had been under treatment, as intimated, for lead colic, and had been somewhat benefited. Previous to admission he had been on several sprees, and at the termination of one of these this state of stupor ensued. As far as we can learn, the week preceding the attack was spent in one continuous debauch. We have therefore a history of lead colic and alcoholism followed by the occurrence of stupor.

The question to consider is, what is the cause of this grave cerebral condition—coma? Head injuries are readily eliminated. There is no history of exposure to great heat. There is no history, as far as we could ascertain, of any disease or of any condition which would lead to the development of meningitis, and on careful examination of the various organs of the body, nothing is found that would give a clue to the cerebral phenomena.

We have, of course, endeavored to determine the condition of the kidneys. The urine presents nothing abnormal either on chemical or microscopical examination. There has been no history of the symptoms which usually precede an attack of uræmic coma. There is nothing to indicate that the man had been suffering from uræmic symptoms prior to admission. It is often said that in uræmia the temperature is subnormal, particularly if attended by depressing circumstances, as in this instance. The temperature has nevertheless been constantly above normal, only twice falling below 99°. We therefore eliminate the possibility of uræmia.

Other conditions which may produce coma can also be excluded. The absence of sugar and acetone from the urine excludes the idea of diabetic coma. The history does not point to this condition. In diabetic coma the case usually terminates fatally in a much

shorter period of time than that in which this case has been under observation.

The question of syphilitic disease of the brain must also be considered. Nothing has been found that would point to previous specific infection. There have been no symptoms to indicate syphilis. In cerebral syphilis, while stupor and coma are present, yet other evidences of grave organic disease precede this state; for instance, a patient will suffer from vertigo, from severe headache and from sleepiness, while convulsions, paralysis (partial or unilateral), tremors, loss of speech and of memory, and impaired mental faculties are usually observed. Symptoms like these were not observed by the relatives, nor by physicians, who treated this man for lead colic. Examination of the eye-ground usually discloses a choked disc or an optic neuritis. In the present instance the eye-ground is perfectly normal, and there is no evidence of fulness either of the arteries or of the veins.

There are no signs of intra-cranial pressure, as from a tumor, meningitis, or hemorrhage. There was not, and is not now, any paralysis, either of sensation or of motion. There was not, and is not, any strabismus, and the pupils are normal and perfectly mobile. At the time of admission they were slightly contracted. Moreover, paralysis of the muscles of the face or of the tongue has not been observed.

The question of the presence or absence of syphilis is often decided by the condition of the various organs of the abdomen. There is no disease of the liver, kidneys, or spleen (amyloid), which would permit an affirmative answer to this question.

In this case also there is no evidence whatsoever of disease of the arteries, a concomitant of syphilis, an antecedent of hemorrhage usually. The radial arteries are perfectly free from atheroma, and the tension is not high. There is no hypertrophy of the heart, which generally accompanies atheroma, and there is no accentuation of the second sound of the heart. The absence of these symptoms, as well as the healthy eye-ground help, by the by, to eliminate Bright's disease.

The diagnosis of lead encephalopathy is determined upon by the history of exposure to lead, by the marked clinical manifestations of poisoning by the metal, and by the exclusion of other causes of coma. While the character of the urine and the absence of the associated pathological lesions permit us to exclude chronic interstitial nephritis, it is well to bear in mind that an arterio-capillary fibrosis accompanies chronic lead poisoning, as well as chronic Bright's disease.

Likewise, the late lesions of syphilis resemble the effects of the long-continued absorption of lead. It is these facts which create so much interest in the analogies of the case, and render its nature somewhat obscure.

Our conclusion, therefore, based upon the history of the case and the exclusion of other conditions, that this is one of lead encephalopathy, is confirmed by the examination of the gums and of the urine. At the time of admission the characteristic lead-line was seen at the junction of the gums with the teeth. This is still present to a slight degree. In addition, the peculiar metallic odor of the breath which is often present in lead poisoning, was extreme, and at the same time the metal was detected in the urine. It is common to find albuminuria associated with lead poisoning. This is not only functional on account of the action of the lead, but also due to an associated nephritis. There is now in the wards a case of chronic interstitial nephritis which has undoubtedly been set up by the action of this poison. Great care, therefore, as before intimated, is to be exercised to determine whether you have to deal with a case of uræmic coma, or of lead encephalopathy.

This grave cerebral state you have just studied is one of the rare manifestations of the deleterious action of lead on the nervous system. Persons exposed to the action of this metal suffer in very different ways. Lead colic is of the most common occurrence. Lead paralysis is also quite frequent. Lead poisoning may show itself by the occurrence of coma, or of convulsions, or of delirium. The delirium is usually mild, but may be maniacal in character. The convulsions are epileptiform, and can scarcely be distinguished from epilepsy, except by the history of the case.

The treatment in this case has been the usual treatment of lead poisoning, that is the use of iodide of potassium. The patient has been given 50 grains of iodide of potassium every 24 hours. Its effects thus far have been most beneficial. Had we not obtained such prompt and decisive results, other means of elimination would have been resorted to. Sulphur baths are of service. Small doses of sulphate of magnesia are often given. As this man is now taking large doses of iodide of potassium, you may ask is not the improvement due to the fact that he is being cured of cerebral syphilis? In the tertiary stage of syphilis large doses of iodide of potassium

are borne in the most remarkable manner. While in the ordinary subject ten or fifteen grains in twenty-four hours will produce iodism, yet in the syphilitic subject from fifty to one hundred grains are necessary to produce the same effect. In this case distinct iodism has been produced. There is a papular eruption on the forehead and on the trunk, and some coryza, both of which are indications that the system is under the influence of the iodide. I can not think that this theraputic test indicates the existence of syphilis; but, on the contrary, I think it most certainly favors the idea of lead poisoning. In cerebral syphilis fifty grains in the twenty-four hours is a small dose, and not likely to produce iodism.

The good effects of this treatment are most manifest. You observe he is quite conscious now, although dazed. A word is sufficient to recall him to consciousness, and he answers questions slowly but correctly. The past week he has recognized friends. He takes nourishment with avidity, and altogether presents a much more hopeful condition than he did two weeks ago.

CHRONIC MYOCARDITIS.

This man is between seventy and eighty years of age. We have been unable to obtain any information in regard to his previous condition. When admitted he had slight œdema of the feet, which had been present for two or three weeks. The patient made no complaints of illness. On examination, we found several interesting conditions, however. In addition to œdema of the feet, there is a little puffiness of the eyelids. This would direct our attention to those organs which are concerned in the production of dropsy. And first, the kidneys. On examining the urine we found a considerable quantity of albumin, but no casts. Examination of the vascular system, which I will now make, reveals an interesting condition of affairs. The pulse is extremely slow, forty beats per minute. It is incompressible. The radial artery is atheromatous. The pulse-wave is sustained for a long time beneath the finger. Atheroma of the other vessels is also observed. For instance, there is a marked murmur in both carotid arteries. There is a rough systolic murmur heard in the abdominal aorta, and also in the course of the femoral arteries. Evidence of the presence of atheroma is also shown by the high arterial tension in the abdominal aorta. On palpation, we find this vessel beating strongly, but there is no thrill, or tumor, or other sign which would suggest the presence of aneurism.

On examination of the heart, we find that the area of cardiac dullness is somewhat increased. It begins above at the third rib. It extends towards the left as far as the nipple line, and towards the right one inch beyond the right edge of the sternum. On auscultation, a murmur is heard at the aortic orifice. This is systolic in time, and high-pitched and rough in character, and is undoubtedly due to the presence of lesions of the aortic valve similar to the lesions of the vessels. At the mitral orifice a low-pitched murmur is heard, which is feebly transmitted in the axilla. The character of the murmur is not such as would necessarily indicate disease of the valve. It might result simply from functional derangement, or from the state of the heart muscle itself. At the tricuspid a third murmur is heard, which is different in character from either of the others. It is undoubtedly due to regurgitation at the tricuspid orifice as a result of dilatation of the right ventricle, particularly as the right heart is enlarged.

There are several points worthy of consideration in this case. From the condition of the aortic valve and of the vessels, we should expect an increased area of cardiac dullness and displacement downwards of the apex of the heart. The increased area of dullness would be in a downward direction. In other words, we should look for hypertrophy of the left ventricle. The cardiac impulse would also be increased. In this instance there is scarcely any perceptible impulse, the percussion area of dullness is increased but square in shape, and on auscultation the first sound is moderately weak. In hypertrophy, you well know, the impulse is strong and visible, the first sound loud and prolonged. The opposite, however, is observed here. Involvement of the heart muscle itself is present, and with the disease of the valves of the heart there is dilatation of its walls and enlargement of its cavities. These conditions are, however, not sufficient to explain the slowness of the pulse, although they do explain the slight albuminuria and the œdema. In dilatation of the heart, the pulse is feeble and its frequency is increased. Therefore there must be something more than the dilatation to explain the slow pulse. Slowness of the pulse is not frequently met with, but when it is present, it is usually due to one of two or three things which could be readily eliminated in this case. Simple slowness of the pulse is often due to jaundice. It is often found subsequent to severe acute diseases, such as typhoid fever and scarlatina. The rate may fall as low as

thirty-five or forty per minute. What the actual cause of this is we do not know, but in all probability it is due to the condition which is present in this instance. Slowness of the pulse is sometimes met with in aortic stenosis. Aside from these conditions, slowness of the pulse is rarely found, except where we have an affection of the heart muscle itself; and from the symptoms and physical signs which this man presents, there is no doubt that we have here that affection of the heart muscle known as chronic myocarditis.

There is no doubt that associated with atheroma of the peripheral arteries, which is marked in this case, we frequently have a similar affection of the coronary arteries. The sequence of such a condition of the arteries is frequently a chronic myocarditis and secondary dilatation. The pathology of the lesions is simple. You well know the condition of the arteries in atheroma, and how readily thrombi may be caused in the vessels, the calibre of which is narrowed and the walls roughened. So in atheroma of the coronary arteries, thrombi are readily produced. Not usually extensive, the area of cardiac muscle affected by the thrombus, together with the effused blood, undergoes the secondary changes common to infarcts. A necrosis of the muscle fibres from local anæmia is set up; and the disintegrating tissue elements create an inflammatory process in the connective tissue resulting in the formation of the sclerosed or fibroid patches which one observes so often at the apex of the left ventricle or on the tips of the papillary muscles. By growth and pressure the proliferating connective tissue causes degeneration of the muscular fibres.

You will recall that we just recorded the presence of a weak impulse and first sound of the heart, and of a feeble pulse. In addition to these physical signs, which indicate degeneration of the cardiac muscle, the patient complains of other symptoms which appear to confirm our suspicions. He suffers from dyspnœa and from attacks of angina. The latter are not extreme, but, since under observation, create sufficient suffering to be worthy of the name. The physical signs, the slow pulse, the dyspnœa and the cardiac pain, are enough to warrant the diagnosis of chronic myocarditis.

The treatment of chronic myocarditis is not possible. The general vascular lesion must be treated, and chiefly by moderate exercise, care in diet, and freedom from excitement, mental or physical. A discussion of the hygienic and therapeutic indications in cases of general atheroma would extend far beyond the hour, and must be reserved for a future lecture.

Communications.

THE VALUE OF QUININE AS AN ANTIPYRETIC IN PNEUMONIA.

BY HIRAM CORSON, M. D.,

of Pennsylvania.

In the Boston *Medical and Surgical Journal* of March 3d, there is an article, or rather synopsis of an article, on quinine in pneumonia, read by Dr. J. H. Ripley before the Academy of Medicine of New York. The reading was followed by a discussion in which seven other members, of acknowledged eminence, gave their experience concerning its value in pneumonia. I was just going to say, "this is a timely paper," but that would not be correct. Such a paper, founded on such knowledge of the utter inefficacy of the medicine to do what it was expected to perform, given to the profession ten years ago would have been timely; would have saved thousands of lives. Even now it is a most valuable paper, and I thank Dr. Ripley and his associates for what they have given to us. The physician who after having read that paper shall again, as he has done before many times, administer quinine in large doses to decrease temperature in pneumonia and in other diseases, will deserve the severest condemnation which the profession can give him. Several years ago a prominent young physican, the son of a beloved friend, was dead from pneumonia, with only three days' illness, and I was informed by those cognizant of the whole treatment, that himself and those who aided him relied on large doses of quinine to save him. Since that time I know that it has been relied upon in many cases all over our country. There are very few physicians with whom I have talked about the treatment of pneumonia, but have *tried* quinine as an antipyretic, not only in pneumonia, but also as a common remedy to reduce temperature in other diseases. I was several times amazed and saddened to learn that many persons, ill with pneumonia, had been allowed to die while the doctors were watching their *trials* of quinine. Trials, did I say? Yes! that is the word. These unfortunate patients, in their peril, had called on their physicians, in the confident belief that they would bring to bear on their cases those remedies which the experience of the

profession had proven to be efficient in controlling this disease, so dangerous to life unless quickly arrested in its course. They had regarded our profession as an honorable one, and therefore relied on it for fair treatment. But their physicians had heard that large doses of quinine were antipyretic—in other words that they would prevent further increase of an already high temperature of the body—yea, even reduce it—and therefore were an important remedy; and though they had often successfully combatted the disease with well-tried remedies, they were glad they had opportunities to *try* the quinine. You say this looks as though they thought the high temperature was the disease? If they did not consider *that* the disease, they at least aimed to cure the pneumonia by the mere reduction of the temperature. Some years ago I saw, somewhere, a doubt expressed by Dr. Oliver Wendell Holmes as to whether the mere reduction of temperature is a matter of any value in febrile affections or not, and it has often seemed to me that it was of trifling importance in many fevers beyond the comfort which it brought.

But what harm was there in *trying* it? They could do it without alarming the patient—they could tell him, if he desired to be bled, that "he had no blood to spare," and that "purging was out of fashion," that "the cough was a good thing to have," that they would give him medicine "that would reduce the heat of his body," etc. Let us see now how the treatment goes on. The patient is fairly affected; his lung is congested in a small part of it—and congestion is but the commencement of inflammation, and both these processes have an ugly way, when they have a "plant," of spreading themselves over more "territory," and of doing it very rapidly, so rapidly indeed that on the physician's second visit, next day, recovery is sometimes impossible, so that even the adorable whisky cannot save him. Bearing this in mind, let us see how the doctor's remedy is confronting the disease. One large dose is given—then wait 8 or 10 hours—then another dose—wait again—the temperature has not fallen, or if from the nausea induced, it has fallen one degree, no relief has come to the patient—but what *has* really happened? Greater involvement of the lung by the disease. In all the time which has elapsed while waiting to *try* the quinine, not the least effort has been put forth to allay the inflammation which was spreading itself throughout the lung, blocking up the air cells and rendering recovery impossible. But where am I going?

Let us now come to Dr. Ripley, who carefully observed the effects of quinine in forty-eight patients from 19 to 45 years of age, commencing in 1877, at St. Francis' Hospital, New York. He "gave it as early as possible in the course of the disease; only in complicated cases, and in those in which the temperature was at least 103°, the thermometer being used in the rectum. No experiment lasted less than four hours, and the majority were continued for from twelve to fifteen hours." . . . . "When a single dose was used in the twenty-four hours it was given in the morning. In twenty of the experiments a single dose of twenty grains was given; and in eight a single dose of forty grains. It was usually given in solution, but in some instances was used hypodermically.

"In two of the patients there was no reduction of temperature whatever noted after the use of quinine, and in two a slight elevation occurred. The reduction of temperature effected by the quinine never lasted for more than from two to four hours." I will give some of his conclusions in his own words:

"1. That quinine was a feeble and uncertain antipyretic in pneumonia.

"2. It in no case shortened the natural course of the disease.

"3. The bad effects produced by it more than counterbalanced the good effects.

4. "It had a bad effect on the appetite and digestion, and not infrequently excited nausea and vomiting.

5. "In some instances the pneumonic consolidation extended under its use.

6. "It was liable to produce marked cardiac weakness, profuse cold perspiration, and profound nervous depression.

7. "That quinine had any effect in preventing cell migration, as claimed by certain authors, he thought extremely doubtful.

8. "We have more efficient antipyretic agents.

9. "In conclusion he expressed the opinion that large doses of quinine in pneumonia should be abandoned."

These excellent conclusions, given to us by a careful, competent, conscientious observer, should be widely known, so that this most fatal practice may cease.

After Dr. Ripley's paper had been read, Dr. Mary Putnam-Jacobi spoke of 100 cases of broncho-pneumonia in children averaging 2½ years. Do I hear my conservative brethren of Philadelphia ask, what business *she* has there? No, I was misled. They did not say anything. Well, this brave, learned

woman came out boldly. Her patients were dispensary people, over whom she perhaps could not keep close watch during the whole course of this disease, for only 59 of them were available for statistical purposes. Seven deaths were *known* to have occurred. Of those not known we have no account; but the conclusion she arrived at was, that quinine was not to be relied on as an antipyretic in the pneumonia of children; and that it was an efficient remedy *only so far as it affected the morbid process present* (italics mine). *That*, it seems to me, would be all that could be desired. "It did tend," she thought, "to limit the *secondary extension* of the disease." When the first extension ends and the secondary begins, is a question I cannot answer; but we fail to do our duty if we do not stop its extension from the first hour in which we begin treatment. The man who knows how to treat pneumonia and applies his knowledge, can do that.

Dr. Fruitnight said, "it had been the common practice to give quinine for almost everything." An honest but sad expression, and a clue to the sad results of the treatment of pneumonia during the last few years.

His experience with quinine as an antipyretic in pneumonia coincided with that of Dr. Ripley, but at the same time he intended to continue its use in this disease, not for its antipyretic, but for its sustaining effect. To secure this it should be given in small doses.

How it *sustains* when the inflammation continues he did not say—probably does not know, but is desirous not to break away from using it too suddenly, for fear of shock.

He said, "one great danger in pneumonia was cardiac failure, and, in large doses, quinine was supposed to have a tendency to produce it." As the term "small doses" is very indefinite now, when from 40 to 70 grains are used in a day, he ought to be well assured that his small doses are not so large as in a certain degree to produce heart-failure. We hope he will soon, like Dr. Ripley, abandon its use entirely.

Dr. F. A. Castle spoke boldly—said, "that his experience fully bore out that of Dr. Ripley as to the uselessness of quinine in pneumonia. Ten years ago Binz had recommended it in large doses, giving as much as 70 grains in 24 hours. Personally he had never carried it to that extent, but had used it in as large quantities as the stomach would bear. He had found, however, that if the temperature was to be reduced by quinine, it must be at the expense of the nutrition of the patient. For the last five years he had almost entirely abandoned the remedy in pneumonia. As regards sustaining the heart, he thought one had a much more reliable agent than quinine in digitalis." How strong is this testimony! What a pity he did not publish it five years ago—thousands are still using the drug, ignorant of its uselessness.

Dr. R. C. M. Page reported Dr. J. Lewis Smith as having said: "He was in the habit of giving one *large dose*, with a view to prevent cell-migration, after which he preferred to give it in doses of from one to one and one-half grains every four hours. It was a useful tonic, and he thought it prevented secondary lesions." It would be satisfactory to know how many grains his large dose contained, and what secondary lesions he feared. There are no secondary lesions in a well treated case of pneumonia. He had just stated that: "This drug was exceedingly liable to excite nausea in children." Why then use a large dose?

Dr. Billington said: "In pneumonia he had been disappointed in quinine as an antipyretic, and he had also found that its use was attended with other bad results. In children, the natural tendency was to recover, both in broncho-pneumonia and in ordinary pneumonia, and a large number of cases would get well without any treatment at all." He forgot, or purposely omitted, to say that under the nauseating quinine treatment, despite the "natural tendency to recover," so flippantly spoken of by many writers, a large number of cases died, as is the case too in the no-treatment practice in true pneumonia. In many cases of so-called broncho-pneumonia, the "broncho" is all there is of it, and they will get well even despite the quinine or in the absence of treatment from—let us agree to say—the natural tendency.

Dr. L. Emmett Holt spoke confidently, as one who knew the subject. I shall quote him freely: "Of twenty cases of pneumonia in children treated by him with quinine or cinchonidia, in twelve the drug was given in sufficient doses and for a sufficient length of time to enable him to form some opinion of its action; and in nine it was a total failure, so far as any effect on the temperature was produced."

"He gave from sixteen to thirty grains a day to children from one to one and a half years old"—not his own children—"and in two or three cases the temperature *rose steadily* after the quinine had been taken. His own feeling was, that as an antipyretic, quinine in small doses was useless, and in larger doses dangerous." I would like to ask how the dear little children bore up under the

thirty grains a day? As large doses are dangerous, whether it was too much for them? But I will leave the inquiry for the present.

"When the fever was high, much better results could be obtained from the judicious and continued use of the cold pack" — a bit of common sense. "By this means he had been able to save a number of children whose cases were apparently hopeless. Unless the temperature reached a very high point, he was doubtful about the efficacy of antipyretic treatment in pneumonia"—the same feeling as that expressed by Dr. Holmes. "For the past two years he had abandoned quinine entirely in acute pneumonia, as he had found that it almost always gave rise to vomiting and other bad results." I am afraid the little children experienced some of these bad results. "Quinine was, however, of very marked advantage in convalescence and in protracted cases of broncho-pneumonia, if given in small doses." Stronger testimony than this by Dr. Holt against the use of quinine, as it is sometimes used in our country, is needless. Dr. Jacobi, the President, who began practice in New York thirty years ago, said: "At that time, and ever since, he had been in the habit of giving six, eight, ten and twelve grains of quinine to children, and it was his practice to administer it deliberately at certain times of the day. He usually gave full doses in two installments in the morning, when the remission occurred—say five grains at eight and five at eleven. If it did not affect the stomach unfavorably, however, he would give a single full dose in the morning." The full dose was I suppose ten grains. For more than fifty years I have had occasion to use quinine in the diseases of children, and know full well how seriously even two or three grains affected some of them; and can readily realize the truth of the assertion made by Dr. J. Lewis Smith that "this drug was exceedingly liable to excite nausea in children:" and the declaration of Dr. Holt, that "it almost always gave rise to vomiting and other bad results." It would have been valuable information to the readers of these reports had Dr. Jacobi given a clear, full account of how the children were affected by so large doses. Whether any of them suffered from vomiting, deafness or other "bad results."

In conclusion, Dr. Jacobi, who had spoken favorably of giving quinine hypodermically, makes the following interesting remarks: "It is not safe to use too concentrated a solution of quinine for hypodermic injection," and he related a case he had met, in which at the autopsy it was found that the quinine was all deposited in the cellular tissue, the water of the solution only having been absorbed." What a valuable hint to us! Is it not probable that, even in the stomach, the solid undissolved quinine—quinine is not entirely soluble in water—is not absorbed, and that we may in that way account for the fact that persons may take the forty or fifty grain doses sometimes given, without greater injury than follows their use?

I have thus thrown together the important facts and opinions of our New York brethren, giving them in the exact words of the reporter, in order that the convictions of these able observers and eminent practitioners, in relation to the utter uselessness —to say nothing of the harmfulness—of quinine, in pneumonia, may be given to the readers of the MEDICAL AND SURGICAL REPORTER.

THERAPEUTICAL NOTES.

BY ROBERT C. KENNER, A. M., M. D.
Of Louisville, Ky.

For some time I have used in practice several emulsions which have proved very satisfactory. They are palatable preparations of efficient therapeutical agents, and I think they may be of service to other practitioners. Emulsions, when properly made and flavored, afford an admirable means of administering many of our most nauseating remedies, notable among which stand cod-liver oil, castor oil, and oil of copaiba. The following, like nearly all properly made emulsions, will separate on standing. It is claimed by some advertisers of proprietary medicine, as an advantage, that their emulsions will not separate on standing. But when we consider that the constituents are of different specific gravity, we are not led to consider it an advantage, but, on the contrary, rather fear the oil is changed into a soap, or that the mixture has been converted into a paste. The palatability is not enhanced, and I cannot think of a single feature of excellence which can be added by its not separating.

An emulsion of castor oil:

℞. Ol. ricini, f℥j.
Glycerinæ, f℥ij.
Spts. menth. piperitæ,
Spts. lavand. comp., āā f℥ss.
M. Sig.—Use in same doses as plain castor oil.

This preparation of castor oil is less calculated to produce emesis than any I have ever seen prescribed.

An emulsion of cod-liver oil and syr. hypophosphites:

℞. Ol. morrhuæ, f℥iv.
Syr. hypophos, f℥ij.
Mucil. tragacanth., f℥iss.
Aq. menth. pip.,
Aq. cinnamomi, āā f℥j.
Spts. lavand. co., f℥ij.
Ol. amygdalæ dulc., gtt. v.
M. Sig.—Dose a tablespoonful.

The following formula is a very palatable and stimulating emulsion of cod-liver oil:

℞. Ol. morrhuæ. f℥iv.
Spts. vin. gallici.,
Mucilag. tragacanth., āā f℥ij.
Ol. amygdal. dulc., gtt. v.
M. Sig.—Dose a tablespoonful.

The syrup of the hyposphites can be added to this formula in this way:

℞. Ol. morrhuæ,
Syr. hypophos.,
Spts. vin. gallici,
Mucil. tragacanth., āā f℥ij.
Ol. amygdal. dulc., gtt. v.
M. Sig.—Dose a tablespoonful.

If the patient should not like the flavor of sweet almonds, compound spirits of lavender, or some other flavoring ingredient can be added. If an oil, it should be added at the expense of the cod-liver oil; and if a tincture, it should be added at the expense of the brandy. It will be found that from half a drachm to two drachms of compound spirits of lavender will give sufficient flavor to eight fluid ounces of the emulsion.

It will be remembered that cod-liver oil preparations stand summer heat poorly, and for that reason have to be kept in cellars or cool places. The mucilage of tragacanth is quite likely to undergo change and become worthless if allowed to stand long in the heat. It may be preserved longer by adding the oil of gaultheria in the proportion of one minim to the ounce. Indeed, it is claimed this will keep it indefinitely. It is well to add this to all of the emulsions, as they turn black when the mucilage undergoes change.

A plain emulsion of cod-liver oil is thus made:

℞. Ol. morrhuæ,
Mucil. tragacanth, āā f℥iv.
Ol. amygdal. dulc., gtt. v.
M. Sig.—Dose a tablespoonful.

An emulsion of castor oil and santonin may be made in the following manner:

℞. Santonin, grs. xxiv.
Aq. cinnamomi,
Spts. lavand. co., āā f℥ss.
Ol. ricini, f℥j.
Syr. tolutan., f℥ij.
Mucil. tragacanth., q. s. ad, f℥ij.
M. Sig.—A teaspoonful contains a grain and a half of santonin. The dose is a teaspoonful every three hours.

The santonin may be added to suit the particular case. If this should not have the proper consistence, pulverized acacia should be added in sufficient quantity. But it is rare for this to occur if the mucilage is properly made, and the emulsion rubbed thoroughly in the mortar. A thorough rubbing is necessary to success in any of these emulsions.

When it is desirable to give a more active purgative, the fluid extract of senna may take the place of castor oil, as in this formula:

℞. Santonini, grs. xvj.
Spts. lavand., co., f℥ss.
Ext. sennæ fld., f℥j.
Syr. tolutan., f℥ijss.
Mucilag. tragacanth., f℥ss.
M. Sig.—A teaspoonful contains two grains of santonin.

The dose is a teasponful, more or less, as the physician may deem proper in each particular case. The same must be said of the amount of santonin, and of the senna in each fluid drachm of the emulsion.

The taste of copaiba is commonly very revolting, and causes much trouble to my patients when they try to swallow this drug without its taste being disguised. I have frequently administered it to persons who had easily-disgusted stomachs, and who had no trouble whatever with it. When it is to be given in gonorrhœa, or for any other purpose, the following formula is a very eligible one:

℞. Ol. copaibæ, f℥ij.
Spts. menth. pip., f℥ss.
Mucil. tragacanth., f℥iss.
M. Sig.—Dose, a teaspoonful.

In chronic bronchitis, I have given the oil of copaiba in combination with other drugs, as in this prescription:

℞. Ol. copaibæ, f℥j.
Syr. senegæ,
Syr. tolutani, āā f℥ss.
Mucil. tragacanth., f℥ij.
M. Sig.—Dose, a teaspoonful.

For children six years old, suffering from chronic bronchitis, I frequently order an emulsion of copaiba with aromatic syrup of yerba santa, which not only completely covers up the taste of the copaiba, but is a very efficacious remedy for coughs. The emulsion is made as follows:

℞. Ol. copaibæ, gtt. lxiv.
Syr. yerbæ santæ arom., f℥ss.
Mucil. tragacanth., q. s. ad f℥ij.
M. Sig.—Dose, a teaspoonful.

These are only a few of the emulsions which can be devised by the physician who has duly before him the importance of

rendering his prescriptions palatable. Many of them can be modified to suit particular cases, and, in fact, that is one of the implied objects of this list of formulæ. Of course, the doses of cod-liver oil, of santonin, and of copaiba, are not here calculated for all cases. Those who use them can adapt them to the cases they have to treat.

Hospital Notes.

CASE OF AINHUM OCCURRING IN THE OUT-DOOR SURGICAL DEPARTMENT OF JEFFERSON MEDICAL COLLEGE HOSPITAL.

REPORTED BY ORVILLE HORWITZ, M. D.,
Demonstrator of Anatomy in Jefferson Medical College, and Chief of the Out-door Surgical Department of Jefferson Medical College Hospital.

This case occurred in a negro, from North Carolina, aged forty-five, by occupation a teamster. He presented himself for treatment during the month of August last. On examination, the little toe of the left foot, owing to atrophy of the metatarso-phalangeal articulation, was found to be hanging by a pedicle, and it looked as though a ligature had been tightly tied around it, causing extreme mobility, which impeded locomotion by reason of the toe getting underneath the foot. The patient stated that he had first observed four years before that the toe was becoming larger, and that it was at times painful. He attributed his ailment to a "stone-bruise," and by the advice of his attending physician, he kept the foot at rest and applied poultices to the parts. He was not improved by this treatment, and some four months after his notice had been called to the condition of his foot, he observed a constriction at the digito-plantar fold. There was great pain on pressure, or on attempting to walk. The metatarso-phalangeal articulation gradually became smaller, but it was observed that as the atrophy progressed the pain began to lessen; at the time that the patient presented himself at the hospital, sensation was far below the normal standard; this was ascertained by pinching, and by inserting a needle in the part. He stated that no member of his family had ever had a similar disease; that he had always enjoyed robust health, and that until the preceding six months he had always lived in North Carolina.

On examination of the diseased part, the skin was found to be much thickened, with the addition of a great deal of fibrous tissue. The adipose tissue was normal. The bones were much atrophied, and the articulations had entirely disappeared. The two digital arteries had become obliterated, and were replaced by an artery which passed directly through the centre of the pedicle. The affected toe was a soft ovoid mass, much larger than normal; the nail was greatly increased in size. There was no appearance of a cicatrix on the foot or leg, nor was there any sign of previous ulceration.

The toe was removed by the knife; a catgut ligature was found necessary to control hemorrhage. The part was then dressed with iodoform gauze. The wound healed rapidly.

The writer has been enabled to find the reports of but three other cases of this singular disease occurring in North America; and, by a singular coincidence, they all occurred in male negroes from North Carolina.

Recent observation seems to confirm the belief that this disease is most probably due to a pathogenic microörganism.

Medical Societies.

THE BALTIMORE ACADEMY OF MEDICINE.

Stated meeting, held April 19, 1887.

The President, Dr. P. C. Williams, in the chair.

Dr. John Uhler exhibited a very simple

Apparatus for Gaseous Injections into the Bowels,

which can be made as follows: Take a tall glass salt-mouth and bore through its tin cover a small hole at the centre and a larger one near the circumference. Through the central aperture pass the neck of a bottle (with a small piece broken out of its bottom) so as to suspend it low down in the jar from a stop-cock on the outside, and slip over this stop-cock good rubber hose to connect it with the long glass tube of a wash bottle which stands in the large hole of the lid like a mustard-pot in a castor. In like manner connect three feet of soft rubber hose to the short glass tube of the wash bottle, and slip its free end over the nozzle of a syringe, with a spring clip near it to exclude air. The whole apparatus is but a combination of well-known chemical contrivances to supply gases automatically and to act by fluid pressure, and we have only to introduce

some lumps of carbonate of lime or magnesia into the generator, and pour dilute sulphuric or muriatic acid into the jar to start it into action. As a rule, it should be made large enough to force out the gas rapidly, and when once charged can be used until all the carbonates in the inner bottle disappear. When freshly charged, the rectal tube should be raised while the stop-cock and clip are partly open to expel the air by carbonic acid, and then the sulphur-water should be rapidly introduced into the wash-bottle and the cork tightly closed while the gas is still passing. By this means we will prevent much contamination of the air by sulphureted hydrogen, and the colic which is due to the admixture of air and gases in the bowels. To absolutely prevent the entrance of air, a third glass tube with a funnel on its top (to be closed by a stopper or glass stop-cock) may be introduced to the bottom of the wash-bottle to fill it with sulphur water; but as every hole in the cork increases the liability to leakage, it is generally better dispensed with. When a small apparatus is used, a Davidson's syringe may be interposed between the generator tube and wash bottle to drive the gas by hand-pressure through the sulphur water into the rectum, but with a good-sized jar the dilute acid alone should do the work. The apparatus has been used with red, white, and various sulphur waters, but he is not satisfied that we at all times get enough sulphuretted hydrogen from them when employed twice a day, and therefore suppliments the gaseous administration by the use of the waters as a drink in the intervals. He also thinks that sulphurated hydrogen is not so readily eliminated from the rectum as is generally believed, since it is nearly always present there flatus, yet we do not often notice it passing as from the breath, giving odor to it. Again if gaseous distention is so frequent in uterine cases, typhoid fever, and when the bowels are affected, is it not reasonable to suppose that a tubercular bowel will offer like impediments to proper absorption? The quantity of gas to be used is also a matter of importance, and if three litres are ordinarily required, then a certain amount of over-distention must ensue and the gas may not after all be entirely absorbed by the rectum proper. The whole subject needs careful scrutiny at the hands of the physiologist to find out if sulphuretted hydrogen in health is not altered in some way by the secretions of the bowels, pancreas, liver, etc., since the gas is so seldom belched and the valves of the intestines are hardly tight enough to entirely exclude it from the stomach, nor is it probable that the whole of the gas is used up in precipitating some mineral constitutents of the food. For the best work it may likewise be important to know whether carbonate of lime or magnesia is more suitable to be used in any particular condition of the bowels, to furnish the gas so as to disinfect, act on, or constringe them, and from a physiological stand point to find out if sulphureted hydrogen is a real disinfectant of the normal healthy body. The importance of this latter question to the hygienist is scarcely to be estimated, since if this gas is found in less quantity in the bodies and fæces of those affected with phthisis or other maladies than in health, it may have something to do with their so-called vulnerability, inheritance or tendency to take certain diseases.

DISCUSSION.

Dr. Thos. F. Murdock thought that sulphur water was objectionable, because it is liable to cause purging.

Dr. P. C. Williams thought that the principal danger of sending phthisical patients to the Red Sulphur Springs was the climate.

Chronic Myelitis.

Dr. P. C. Williams reported a case in which he prescribed iodide of potash, bromide of potash and sulphate of strychnia in the same prescription. The case was one of chronic myelitis, caused by syphilis in a man who had contracted it from his wife, who in turn took it from a midwife. The druggist sent the bottle to his office and said the incompatibility of the ingredients had caused a precipitate of the iodide of strychnia. Dr. Williams said he had not known of the danger of such a compound, and simply related it here to warn others.

Dr. Uhler was uncertain what the precipitate was, but thought that, although chemically incompatible, the prescription would be therapeutically active if the bottle were thoroughly shaken before taking each dose.

Dr. Bombaugh thought there was too little sulphuric acid in the sulphate of strychnia to cause any remarkable change.

Dr. Canfield read a paper on

Some Complications of Chronic Endarteritis.

Dr. W. P. Chunn read a paper on

Treatment of Retained Placenta.

DISCUSSION.

Dr. B. B. Browne thought it might be generally correct to remove the placenta, but in cases where the placenta had been retained for a long time before coming under obser-

vation, and when the woman had septicæmia, he doubted whether she could stand such an operation. He thought it was the best plan to run the chances for the woman, and remove the placenta if possible.

Dr. Bombaugh spoke of the method of dealing with retained placenta among the Indian tribes in the far West. Dr. Woodward, who is employed by the Department of the Interior among the Dacotahs, was called by an Indian midwife to a case of retained placenta. Reaching his hand under the blanket of the squaw, he found a heavy stone attached by a string to the cord. On inquiry as to its meaning, he learned that the woman had been marched up and down the lodge for hours with the weight tugging on the cord, until she became exhausted. He also learned that this manner of removing a retained placenta is customary among the Indians. Dr. Woodward had obtained no data as to results, but was told that the rate of mortality was favorable.

Dr. Uhler asked how many cases of death from septicæmia after abortion the gentlemen had seen.

Dr. Chunn had never a case, because he had treated all by scooping out the placenta.

Dr. Browne thought there was no doubt that many had died in this way. In fact, he could recall cases which died in this way, in his early career, especially at the time of Dr. Buckler Jones, who produced miscarriage in women.

Dr. Uhler could recall no such cases.

Dr. Murdock thought Dr. Browne was not answering Dr. Uhler's question. Dr. Uhler meant natural abortion. Dr. Murdock used ergot and the tampon, and thought it was much safer than to dilate the uterus.

Dr. Williams thought that two interesting points had been brought up; one by Dr. Browne, who suggested letting the woman run the chances. He thought at times the placenta should be removed. The other point was by Dr. Chunn. Dr. Williams asks if it is good practice in every case to dilate the uterus and remove the placenta. This is open to question. When there is no fever, he lets it alone. He has never seen a death after miscarriage, either from septicæmia or hemorrhage. He advocates letting the woman alone until some pathological symptoms appear.

Dr. W. C. Van Bibber said he had never seen death after miscarriage.

Dr. Thos. B. Evans made the same statement.

Dr. Taneyhill thought a conscientious physician was uneasy until the placenta was out, and he was in favor of using an instrument to remove it. He reported a case in which a woman would not allow the use of an instrument; so after three weeks he put in a tampon with belladonna just before her time, and then gave aloes and myrrh with senna, and she delivered herself of a large placenta, which was so mouldy that he could hardly recognize it. Dr. A. C. Abbot made an examination of it. In another case he used the placental forceps as dilators.

Dr. Chunn agreed with what Dr. Taneyhill said.

Periscope.

Points in the Diagnosis of Brain Diseases.

Nothnagel, in an article read recently before the College of Physicians of Vienna, gave the following diagnostic points on the value of headache as a symptom of brain disease:

1. In brain tumors headache is of very little value in diagnosis; we know that the cerebral substance is not sensitive; the pia mater but little sensitive, and the dura mater only, of the cranial contents, is sensitive. Headache occurring in cases of cerebral tumor is explained by tension upon dura caused by the bulk of the tumor.

2. Headache is present in inflammatory processes situated in the meninges, and more frequently in lepto-meningitis than in pachymeningitis; in lepto-meningitis the headache frequently changes its characters.

3. Headache is present in chronic cerebral hyperæmia and also chronic anæmia; it is questionable whether anæmia alone is the important element in chlorosis, as we see most marked cases of pernicious and intensive anæmia caused by carcinoma in which headache is absent. Headache is rarely present in insular multiple sclerosis; in cerebral abscess its presence and character are extremely variable. The location of the headache gives no certain diagnostic point

for the determination of the location of the lesion, although in general terms it may be said in the majority of cases the lesion is where the headache is.

Vertigo, while common in various cerebral diseases, is of little importance; when it is excessive and accompanied by incoördination, such as occurs in diseases of the crura of the cerebellum, it has decided import.

Vomiting is rarely of great value in diagnosis; it aids chiefly in the location of lesions. It can be present in cases in which the amount of blood in the brain is abnormal, and an irritation of the centre of emesis in the medulla oblongata exists.

We are aided by this symptom in diagnosticating lesions of the tissue in the posterior fossa of the skull; for example, tumors which originating in the cerebellum, press upon the medulla; or tumors of the medulla or pons.

Fever is an important symptom in but few cerebral diseases. The highest temperature is present in meningitis, especially in its infectious form. But as peritonitis without fever is often observed, so meningitis may run its course without marked rise of temperature. Fever occurs in cerebral abscess and septic phlebitis of the cerebral sinuses; it has then more often the characteristics of septic fever with pyæmic chills, and does not depend directly upon the phlebitis, but upon pulmonary embolism. Fever also occurs in the course of progressive paralysis. The pulse gives no certain criterion for the diagnosis of a given cerebral disease. It is often, however, of no value in the abnormalities of its rhythm in beginning meningitis, in the form of regularly occurring *arythmie* (first described by Nothnagel), where a certain periodicity in the variations of the pulse frequently occurs; the increased number of beats endures but a few moments, and is caused by an irritation of the pneumogastric nerve. The respiration gives no information in the diagnosis of brain diseases.

Regarding disorders of speech, aphonia is seldom present, and the location of the lesion which could cause it, in the medulla oblongata, is such that death generally results speedily in these cases. Speech is affected most often in progressive bulbar paralysis, and frequently in multiple sclerosis in patches. Speech is also implicated in progressive paralysis when the origin of the hypoglossus is affected; also in cortical disease of the lower portion of the central gyrus—*Wiener Medizinische Presse, No.* 13.—*Medical News, May* 14, 1886.

Illustrations of the Occurrence and of the Gravity of Diabetes Mellitus in Early Life.

Dr. T. McCall Anderson reports the following interesting case:

In the April number of the *Glasgow Medical Journal*, an interesting case of diabetes mellitus, in a girl nine years of age, is reported by Dr. William Frew, of Kilmarnock, and he there remarks upon the extreme rarity of the disease in children under ten years of age. In this connection, the following cases will be of interest:

On the 7th of July, 1881, on the recommendation of Dr. McGowan, of Millport, a gentleman called upon me, bringing with him a specimen of his daughter's urine. She was two years and three weeks old, and between five and six weeks before his visit she began to droop; her appetite also failed somewhat, and she suffered from thirst, with progressive loss of flesh and strength. Her urine was pale (its quantity I could not ascertain), its specific gravity was 1038, and it was loaded with sugar. She died (9th July) two days after her father's visit to me, and before I had the opportunity of seeing her—*i. e.*, within six weeks of the onset of her illness. A post-mortem examination could not be obtained.

On the 8th January, 1884, I was requested by Dr. Edward M'Millan to see with him a little girl $2\frac{1}{2}$ years old, who had previously enjoyed good health. Nine days before this time she fell, alighting upon her hands, and was not supposed to have hurt herself at all. The following day, and more or less thereafter, she suffered from the most intense consuming thirst, with profuse urination, and a tendency to coldness, lividity, and collapse. The day before my visit, she was reported to have vomited everything.

When I saw the child, I found that the vomiting had ceased, but that the other symptoms had continued. The pulse was of fairish strength, but was distinctly irregular as to force and time; there was some emaciation, and the temperature registered 95° F. The quantity of the urine could not be ascertained, but it was very pale, intensely acid, specific gravity 1037, contained a slight trace of albumen, and a large quantity of sugar, the quantitative analysis with Fehling yielding 5 per cent. There were no head symptoms whatever. The treatment recommended was the administration of warm fluid food—saccharine and amylaceous matters being avoided—nutritive enemata, external warmth, and a teaspoonful of brandy every hour. Granules of morphia ($\frac{1}{100}$th of

a grain) were to be continued and cautiously pushed. The day following my visit, Dr. M'Millan wrote me that although the temperature the previous evening rose to 99.8° no improvement in the symptoms occurred, ond that the child gradually sank and died at 3:30 p. m. on the 9th of January—*i. e.*, 9 days from the first commencement of the symptoms.

A *post-mortem* examination was made by Drs. Coats and Steven, the brain being carefully examined, but nothing was found, with the exception of slight anæmia of the brain, and some fatty change in the renal epithelium, such as might be accounted for by the intense diuresis.—*Glasgow Medical Journal, May,* 1887.

The Case of Catalepsy Now at London.

Science for April 22, 1887, describes the following case which is now exciting great interest in London:

The case of M. Chauffat, a native of Haute Savoie, who has been overtaken by a trance in a French hotel in London, has been exciting very great interest among the section of medical men devoted to psychological studies. This is the seventeenth day of his cataleptic condition, from which he shows no sign of awakening, and the administration of food is not a little difficult. Chauffat has been a patient of the famous Dr. Charcot, in the Salpêtrière Hospital in Paris, where a large number of experiments are now being conducted upon hypnotizing. Dr. Charcot, however, particularly wishes it to be understood that Chauffat is not a hypnotized subject. The general state of his body is good, the temperature and pulse being normal, though the respiration is subject to great variation, changing from 15 to 28 in the course of a few hours. The only way in which he can be aroused sufficiently for the administration of food is by directing a strong ray of light on his eyes. An examination of them by the eminent oculist, Mr. Brudenell Carter, showed that all the vessels, both veins and arteries, were much contracted and very small. Both sides of the body are alike in their condition, though the cataleptic condition is stronger in the limbs than in the trunk. The most extraordinary feature of the case is the remarkable results obtained by gently stroking Chauffat's arm. The limb if raised upright, remains in that position indefinitely; and, when certain nerves are stroked, the fingers clutch tightly, the blood is forced from the extremity, the hand and forearm turn slowly round to the right till the strain is so great that the muscles stand out rigidly, the limb being perfectly rigid. On the other hand, the most gentle touch or stroking of the flexor of the forearm is sufficient to relax the whole. Without doubt, Chauffat's case is one of the most remarkable of the kind that have occurred in England, although they are more frequently to be met with in France.

Rumination in Man.

The *Journal de Médecine de Paris* publishes a communication made by M. le Juge de Segrais to the Sociéte Médicalé de l'Elysée concerning rumination in the human subject. The author records a case, observed by M. Axel Johannesen, of a peasant, aged 27, who was subject to frequent epistaxis. He chewed his food imperfectly, and it returned to his mouth automatically from five to fifteen minutes after meals; he then masticated it a second time, the proceeding being attended with a pleasurable sensation. Rumination lasted from fifteen to forty minutes. After a slight meal, or when the man was angry, these phenomena did not appear. Recently the patient suffered from dyspepsia, with tenderness in the epigastric region. The stomach was washed out and the indigestion was relieved, but the rumination continued. The case observed by M. le Juge de Segrais himself differed from the one above described in that there was no second mastication. The patient, a child, aged 11, had contracted the habit of causing food to return into the mouth, in order to renew the pleasure of any thing the taste of which he liked. In order to effect this, he first recalled the taste of whatever he had most enjoyed in his meal, then held his breath, and, by contraction of the abdominal muscles brought the particular thing which he wished to taste again up into the mouth; he occasionally did this a second time. On examination, the stomach was found to be slightly dilated, but made no rumbling sound; the child was pale, and rather anæmic. His parents had tried every means of curing the habit. When a young child he lived in the country, and milk was his principal diet; the stomach became overloaded, and regurgitation ensued. The child became accustomed to these regurgitations, which finally caused a pleasurable sensation, and the habit of rumination was thus established. M. le Juge de Segrais proposes to submit the patient to a course of hydrotherapy, to wash the stomach out with Faucher's apparatus, and to apply the actual cautery to the epigastric region.

The Treatment of Erysipelas.

Dr. Robert Pollok writes as follows in the *Glasgow Medical Journal* of May, 1887:

I am of opinion that the treatment must depend upon the type of the disease.

In all the cases I have seen, the treatment demanded was a stimulating one. I refer to simple general erysipelas. But in localized erysipelas affecting the throat, ear, and pharynx, aconite in small doses, frequently repeated, as recommended by Ringer, has been productive of the happiest effects when administered at the beginning of the attack. I will take as a typical example of simple cutaneous erysipelas that form which we so commonly see, commencing over the root of the nose, and spreading over the face and forehead. In such cases, I immediately begin the administration of 20 to 30 minims of tinct. ferri mur. (diluted of course with water) every two hours; and as a protective and palliative, I use the following preparation:

℞. Gutta percha, ℥ij.
Chlorof. meth., f. ℥ij solve.
Zinc. oleati, ℥ij.
Iodoformi, ℥ss.
M. Sig.—To be painted over the part affected.

The advantage of this preparation over the powdered starch, zinc, or flour, is its comeliness. Of course, previously to applying this preparation, I have the parts carefully washed with tepid water, and often when there is much pain I use the decoction of poppy heads as a fomentation. This treatment usually effects an amelioration of the symptoms, and the disease subsides. But in some cases the course of the disease does not stop here, it runs riot all over the head and neck, and the medicinal treatment then pursued is ammonia, bark, iron, and quinine, with perhaps a grain of solid opium to obtain rest. I am happy to state that I have never lost a case of eysipelas, although the duration and severity of the complaint have varied much.

The *rationale* of the local application above mentioned must be purely protective and palliative, by excluding the irritating effects of the cold air, and not by excluding specific germs. The latest researches prove that the schizomycetes or streptococcus erysipelatosus is anærobic, or flourishes where air is excluded, living in and upon the tissues affected.

Puncture of Abdomen for Flatulent Distension.

Dr. W. O. Priestley in the *Lancet* gives notes of a case which were sent him by Surgeon-major Franklin, in India. The patient, after a long and tedious labor, suffered from an enormously distended abdomen, with constant vomiting, some dyspnœa, occasional rigors, and signs of exhaustion. All the usual remedies having been tried to relieve the distension, which was threatening the life of the patient, the ascending colon was punctured with a small trocar. The gas made a whistling noise as it passed through the canula. By pressure the greater part of it was expelled, and a binder adjusted, with immediate relief. A second puncture was made 48 hours after the first and was also followed by relief to all the distressing symptoms; the temperature rose to 102°, however, and for ten days the case caused some anxiety, but after that time improvement was steady. Tapping the abdomen for dangerous retention of flatus is a well known remedy in some of the ailments of domestic animals, and is said to be practiced on sheep when they have "blown themselves," that is, when they have eaten too largely of a succulent pasture or of some improper herbage. There are various records where the intestine has been punctured in the human subject for extreme distension. Mr. Bryant in 1873 published a case of hernia with intestinal distension, where punctures were made in the bowel without bad result; there was no escape of the bowel contents, and only a drop of blood. That the proceeding is ordinarily innocuous enough is shown by a case under the care of Dr. Broadbent, in which the patient was tapped for flatus about 28 times. Prof. Fonssagrives, *Gaz. Hebd.*, 1877, says he has seen intestinal puncture practiced by Nelaton, Blache and Velpeau, and that "it is a sovereign operation in some cases, and not dangerous even when there are multiple punctures."

Relations between the Thyroid and Cerebral Circulation.

The impetus which the description of the condition known as myxœdema has given to the study of the thyroid gland has received an additional illustration in a note by Professor Waldeyer (*Berl. Klin. Woch.*, No. 14), calling attention to the arterial supply of that organ and its apparent relation to that of the brain. He points out that Stahel recently showed that the superior thyroid artery bore in the degree of its development a constant relation to the "bulbus caroticus internus" (Krause), whereby the amount of blood transmitted through in the internal carotid in its winding course along an osseous channel could be regulated. Now the ver-

tebral artery, in its course to the base of the brain, has a somewhat analogous disposition, both as regards tortuosity and relation to bone, as the carotid, and it is justifiable to infer that a similar relation to the above obtains between the inferior thyroid and the vertebral. This idea implies that the thyroid body can act as a sort of reservoir for blood, protecting the carotids and vertebrals from too great an influx. The great vascular supply of the thyroid is remarkable in proportion to its size; it receives large arteries and has a plexus of veins, which are in close connection with the great venous trunks. The capillaries of the thyroid are also peculiarly disposed for the rapid removal of blood. Comparative anatomy lends support to the doctrine, the general fact being that in most mammals the brain is chiefly nourished by the internal carotid, and that in these animals both superior and inferior thyroid arteries arise from the common carotid trunk. Professor Waldeyer disputes the statement that the thyroid is exceptionally rich in lymphoid tissue, and refers its abundant nerve-supply to the large number of blood-vessels it contains.—*The Lancet, April* 30, 1887.

On the Treatment of Tetanus.

Dr. A. Hiller, of Breslau (*Centralbl. f. Chir.*, 27th November, 1886), argues that the mode of death in tetanus is by hyperpyrexia, and that, therefore, successful results might be expected from an antipyretic method of treatment. Very high temperatures do occur in severe cases of tetanus, 43° C. (109.4° F.) and slightly upwards being not uncommon shortly before death. Wunderlich found in one case a temperature of 44.75° C. (112.5° F.) shortly before death, rising to 45.4° C. (113.7° F.) shortly after death. The hyperpyrexia is apparently due to the excessive and continuous muscular action. The relationship between the abnormal muscular action, hyperpyrexia, and death, appears to be proven by experiments upon dogs by E. Leyden and Ch. Richet, who produced in them artificial tetanus by direct electrization of the spinal cord. Hyperpyrexia to the extent of 43° C. (109.4° F.), from whatever cause proceeding, he holds to be in itself dangerous to life, and a rise to 44° C. (111.2° F.) probably inevitably fatal. The first indication, therefore, in the treatment of tetanus, is to reduce the temperature, which would at least hinder a fatal termination, and relieve much of the patient's suffering. The use of cold water in any way is of course out of the question. Dr. Hiller would try tepid baths, about 86° F., but would rely most upon antipyretic drugs, such as thallin and antipyrin, aided by subcutaneous injection of pilocarpin. It does not appear that he has actually treated any cases in this way, but he discusses the method in detail, and commends it to the attention of hospital surgeons.

Amputations of Fingers Under Cocaine.

Dr. Nelson L. North, Jr., of Brooklyn, calls attention in the *Annals of Surgery*, May, 1887, to a method of employing cocaine in cases in which amputation of the fingers is necessary.

The injuries for which he has usually had to amputate were caused by stamping machines or circular saws, and his operations varied from amputation of part of the last phalanx to that of the greater part of an entire finger or thumb.

His method is as follows: On the entrance of the patient the wound is thoroughly saturated with a 4 per cent. solution of hydrochlorate of cocaine before any examination is made. After waiting a few minutes for absorption to take place, the injury can be examined and the wound probed with entire satisfaction, as the patient makes no resistance, because he suffers no pain. Flaps may then be cut, following each considerable incision with a few drops of cocaine solution, also using it occasionally to wet the entire part. Ligatures may be applied, and the bone sawed as necessity may demand. After thoroughly irrigating the wound with antiseptic solution and providing for proper drainage, sutures may be applied and the wound dressed acording to the principles of antiseptic surgery.

The method is simply one of saturating the wound with the cocaine solution—the cocaine is not injected, anæsthesia being sufficient without the use of the hypodermic needle.

The Statistical Horror.

J. Stuart Nairne, F. F. P. and S., Glasgow, writes as follows in the *Edinburgh Medical Journal* for May, 1887:

And now for the statistical horror, over which I shall linger only for a few moments to emphasize my distrust, my disgust, and my contempt for statistics as statistics. Does one man want to belittle the work of another?—he points out, disingenuously of course, his percentage mortality. Does he

want to laud his own work?—he points triumphantly to his own recovery list. And who is to know really the difference between them? Has the first man, like a brave pilot, endeavored to steer every shattered bark that has come across his path into some peaceful harbor?—not always successful, perhaps not even often successful, but always daring, kind, generous, and shedding at least a little "kindly light amid the encircling gloom." Laborious, painful task of him to be recognized honorably by few as a hero, but supported in his inmost soul by honest conviction that here is a great work to be done "without money and without price," he, indeed, has the reward within. But the other, abandoning to the wild waste of waters every apparently sinking ship, can bring into port, with flying bunting and at beat of drum, an apparantly dishevelled, but not otherwise endangered craft.

The Fertility of Women.

Schbankow concludes as follows in an article in the *Zeitschrift für Geburtshilfe und Frauenkrankheiten:*

His investigations were upon the influence on the fertility of women exerted by absence, at different intervals, of their husbands. In certain districts of Russia the greater portion of the male population of the villages is obliged to seek work in other localities during the summer, twelve per cent. of the entire population thus temporarily emigrating.

Women whose husbands remained at home during the entire year averaged 9.2 children each, excepting the sterile women, who were 3.33 per cent. of the whole number; women whose husbands left their homes to procure work averaged 5.2 children each, excepting the sterile, who were 11 per cent. of the whole number.

The writer finds the cause of these facts, not in bad hygienic surroundings, but in the severe manual work which falls upon the women in the absence of the men, tending to produce uterine disease and facilitate abortion, and also to produce amenorrhœa; in the interruption of the sexual relations thus produced; and in the frequency of syphilis and other venereal diseases, as contracted by men in strange towns, and communicated to their wives.

How to Check Bleeding From the Nose.

The following suggestion, which is now going the rounds of the medical journals, is so useful, as we know from repeated experiences, that we think it worth while to give it room in our columns, although it is neither new nor infallible:

In persistent hemorrhage from the nose, plugging the posterior nares should not be done until an attempt has been made to check the hemhrrhage by firmly grasping the nose with the finger and thumb, so as completely to prevent any air from passing through it. This simple means, if persisted in, will in many cases arrest the bleeding. The hemorrhage often continues because the clot which forms at the seat of rupture in the blood-vessel is displaced by the air being drawn forcibly through the cavity in the attempt of the patient to clear the nostrils. If air is prevented from passing through the cavity, the clot has a good chance to consolidate, and the hemorrhage is likely to cease.

A Novel Uterine Dilator.

Dr. C. P. Wilkinson, of New Orleans, reports in the *New Orleans Medical and Surgical Journal* for May, 1887, an interesting case of labor delayed by rigidity of the os uteri, in which he effected dilatation by introducing into the uterus a rubber condom, upon a female catheter, and distending the former by means of a tube connected with a fountain syringe. The bag of the fountain syringe was raised about two feet. It was found that the patient could not bear an uninterrupted pressure, on account of the pain it produced, and Dr. Wilkinson imitated nature by raising the bag of the syringe during the pains, and lowering it during the intervals between the pains. By this means he made his artificial bag of waters act like a natural bag of waters, and even supplement the efforts of nature to produce dilatation during pains, and relieved his patient of the strain at the times during which nature relaxes her exertions.

A Rational Treatment of Catarrh.

Dr. George W. Major, of McGill University, in a recent lecture, calls attention to the popular abuse of salt solutions in the treatment of nasal catarrh. He says he will not say there is nothing worse—for there is—and that is simple water used at any temperature. The membrane of the nose is hygroscopic, or capable of absorbing moisture, and that tendency is increased when in contact with liquid of low specific gravity; the result is that the vessels become loaded, the membrane tumefied, and the surface irritated. A solution of salt in water, if of proper density, is not subject to this grave disadvant-

age, but it relaxes the membranes in time and produces a genuine nasal catarrh where possibly none previously existed. The cleansing solution which he finds most generally serviceable, is composed of carbolic acid, gr. j.; borax, gr. iij.; sod. carb., gr. iij.; glycerine, ʒj.; water, ʒvij.

Direct Inoculation of Tuberculosis in Alaska.

Dr. Pitcher relates the following personal observation among the natives in Alaska:

The native population is, and has been for some time, steadily decreasing. It is true that an epidemic of small-pox some years since contributed largely to that end, but not to such an extent that the ravages of consumption were lost sight of. The sudden onset of the more alarming symptoms in the respiratory and circulatory organs may be in a measure explained by the almost universal stooping entailed in "packing" immense loads upon the back by means of a band passed across the chest horizontally, and attached to bands at either extremity, passing from the load, under the arms, in front of and over the shoulders, back to the load again. This, as a matter of course, renders breathing a difficult feat. The dampness of the climate, lack of good hygienic surroundings, intermarriage with Russians, and syphilis and scrofula, may explain the existence of the disease, but not its rapid spread and presence throughout whole families. One would expect to find among a people accustomed to a climate from infancy, taking plenty of out-door exercise, living extensively upon a diet of fats and oils, and remarkably free from gastric disturbances of any type, a certain percentage free from it, but such is not the case; it is the exception, rather than the rule, to find a man, woman, or child free from it. After examining a large number of cases, young and old, it struck me that some unusual agency must be at work, but look where I would, no remarkable explanation could be found, until I chanced to be in a house visiting a patient during the preparation of the of the evening meal. The klutchman (wife) was assiduously chewing a mass of something, spitting it, when thoroughly moistened, into a spider. Watching more closely, the substance chewed proved to be a sea-weed, prepared in the fall by pressing into square cakes and drying. This she picked to pieces and thrust into her mouth, masticating it as described. The spider at last becoming full, a quantity of seal or herring oil was poured over it, a few hot coals stirred in, and later warmed slightly over a fire. Of this delicate dish the entire family partook briskly. This klutchman was a consumptive, and the patient (her son) was also suffering from the same complaint.

Artificial Digestion.

Prof. E. A. Wood, M. D., in a suggestive lecture at the Western Medical College, of which an abstract is published in the *Pittsburgh Medical Review*, April, 1887, discusses the proper use of artificial digestives. He recognizes the fact that there are conditions in which artificial digestion is absolutely necessary to tide a patient over a brief space of time. But he thinks that, with these exceptions, such a practice is inefficient and pernicious. Food so administered does not supply normal nutrition, but is only an expedient, furnishing a little succor to the starving garrison, until the siege is raised and the gates are thrown open to the real commissariat.

Some people, if kept in idleness, will grow lazy and make no effort. Our pauper asylums afford plenty of such examples. If the right arm is not used it will waste, and lose not only its vigor, but the relish for exercise. The same is true of the digestive organs: if they are not exercised they will atrophy, and even cease to work at all. If a pauper is made of the stomach, by vicarious digestion, it will lose its vigor and its functions. Pampering and keeping the digestive organs in enforced idleness, so far from curing indigestion, aggravates and establishes the mischief. The cure for indigestion, except the form of indigestion belonging to acute diseases, is to compel the digestive organs to perform their work for themselves, and not by having that work done in some other way. The true way to maintain healthy digestion is by giving the digestive system physiological work.

On the Excess of Male Children when Conception Occurs at the Time of the Post-Menstrual Anæmia.

(*Arch. f. Gyn.*, XXVII., 1.)—The first question Furst endeavors to answer is as to the time and cause of differentiation of sex in general. The conclusion reached is that it is highly probable that the differentiation may occur before, during, or a little while after impregnation; that the chances of the development of one or another sex in one and the same woman may vary before final differentiation occurs; and that the ultimate cause will be all the more powerful

the less the previous ones have had a marked leaning in one or another direction. The cause of differentiation he believes resides largely in the good or bad state of health of the parents, there being an excess of females in the first instance, and of males in the latter, speaking relatively.

The second question which he considers is the excess of male births in cases of conception during the post-menstrual anemic state. He has investigated 193 cases carefully in regard to the probable date of conception after menstruation, and there is a notable increase of male births over female in the cases where conception probably occurred within the first five days after menstruation; that is to say, when the woman is not so well nourished as later, when the uterus is more congested.—*American Journal of Obstetrics*, May, 1887.

Examination of the Hip-Joint Through the Rectum.

Valuable information as to the condition of the acetabulum may be obtained by examination with the finger in the rectum. Three cases are reported by Schmitz in the *Centralblatt für Chirurgie*, in which this mode of examination proved useful. The patients were children, from three to five years of age, in whom symptoms of coxalgia had existed for three, six, and twenty-one months respectively. In all three the thigh was slightly flexed, abducted, and rotated inwards. In one case rectal palpation revealed a well-defined tumor in the acetabular region, in the others abscesses varying in size from a hen's egg to a nut were detected. Movement of the femur during anæsthesia produced no friction. Resection was performed in all the cases, and the head of the femur, with its cartilage, was found to be quite healthy, but the acetabulum was extensively diseased. Schmitz recommends the use of this method of examination in all cases of suspected hip-disease.

Drainage With String.

Dr. A. R. Jenkins, of Henderson, Ky., recommends, in the *Annals of Surgery* for May, 1887, the use of rough string, rendered aseptic by immersing it for an hour in a solution composed of corrosive sublimate, 1 part; glycerine, 50 parts; alcohol, 100 parts; water, 150 parts. The string may be kept in hermetically sealed jars. In use one end of the string is drawn through a drainage tube of India-rubber of suitable size, and then the tube is introduced into the wound to be drained, and more of the string is drawn in from day to day as required, while the soiled portion is cut off. The advantage claimed for this material for drainage is that it is very hydroscopic, and that if the ends are kept covered with gutta-percha paper, or Lister's oiled silk, the string will not become glued. Dr. Jenkins points out the need to keep the end of the string which is to be drawn into the tube clean and aseptic.

Reviews and Book Notices.

BOOK NOTICES.

Thomsen's Disease (Myotonia Congenita.) By Dr. Geo. W. Jacoby.

Transplantation of a Rabbit's Eye into the Human Orbit, by C. H. May, M. D.

Certain Causes of Sterility in the Female, and their Treatment, by Egbert H. Grandin, M. D., of New York.

Practical Examples in Prescription Writing, by Charles H. May, M. D., of New York. A very suggestive pamphlet.

A Review of Twenty-two Cottage Cases Occurring in the Women's Hospital, in the service of Dr. T. Gaillard Thomas, by A. H. Buckmaster, M. D.

Feeding Patients Against the Appetite, by Ephraim Cutter, M. D., M. M. S.

An instructive series of cases illustrating the advantages of "forced alimentation."

Oration Delivered Before the Alumni Association of the Medico-Chirurgical College of Philadelphia, on the evening of Thursday, April 7, 1887, by Dudley S. Reynolds, A. M., M. D., Louisville, Ky.

Gathering of the Waters, or the Evolution of Seas and Rivers. By D. T. Smith, M. D., Lecturer on Medical Jurisprudence in the University of Louisville, and one of the editors of the *Practioner and News*.

An Introduction to Practical Bacteriology. A Guide for Students and General Practitioners, by Thomas E. Satterthwaite, M. D., Professor of Pathology and General Medicine in the New York Post Graduate Medical School and Hospital, New York City.

This is one of that timely, practical, and essentially American series, "The Physician's Leisure Hour Library," published by Geo. S. Davis, of Detroit. It presents very clearly the data necessary for the prosecution of bacteriological research by the physician.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER will be published in each number. The regular edition for this week is 4,000 copies.

A PERSONAL STATEMENT.

We are in receipt of inquiries regarding the change in the management of the REPORTER. In response to these inquiries, we would state that THE MEDICAL AND SURGICAL REPORTER is the property of the son and daughter of the late S. W. Butler, M. D., in whose interest it is now conducted by us. The retirement of the former editor was consequent upon the expiration of his contract with the proprietors. Upon assuming control of the REPORTER, we offered to Dr. B. the use of its columns to take leave of its readers. This offer was declined.

In the issue of May 7th we indicated our appreciation of the conduct of the REPORTER in the past, and our intention to adhere to the general methods which have contributed to its success.

We purpose also to make certain improvements in the REPORTER, which will increase its worth to its readers.

To our contributors we wish to announce that hereafter all original communications published in the REPORTER will be paid for. This, we hope, will prove an incentive to many good writers and shrewd observers who otherwise could not well spare the time to give their observations and opinions to the medical public.

We hope by our management of the REPORTER to keep all its old friends, and with their aid to make it a fit representative of the practical, conservative, and intelligent sentiment of the American medical profession.

THE TREATMENT OF SCARLET FEVER.

There is an impression among medical men who belong wholly to this generation that the methods of treatment adopted by those of a generation or two ago were invariably heroic. Bleeding, purging, blistering, etc., come to the mind when we think of our forefathers, and we are too apt to imagine that rational expectant or symptomatic treatment is a modern idea. This is a grave error, and does great injustice to those wise and thoughtful men who long ago often arrived, by a marvelous use of their opportunities of observation, at conclusions which are only confirmed by a use of the better means of precise study which this age enjoys. Opinions which are every day being put forth, bearing the marks of clear thinking, and worthy of the best advances of modern medical science, have been anticipated long since by those whose names are historic.

These reflections have been evoked by the reading of an admirable lecture on the treatment of scarlet fever, by Prof. Frank E. Waxham, M. D., of Chicago, which is published in the *Philadelphia Medical Times*, May 14, 1887. In this lecture Dr. Waxham describes with great judgment the principles which should govern the prophylactic, hygienic and medicinal treatment of this disease, and, in addition to other suggestions which experience has demonstrated to be useful, points out the importance of restricting the use of medicines as much as possible, and of chosing among those to be used such as support the system and assist the excretory organs. The more reliable remedies are dig-

italis, solution of the acetate of ammonia, tincture of the chloride of iron, and water. The latter he advises to be used freely, internally and externally. He concludes his lecture by recommending action upon the skin by diaphoretics; using the sweet spirit of nitre, or spirit of Mindererus. He directs attention to the point that the sweet spirit of nitre is a powerful diaphoretic, as well as a cardiac and cerebral stimulant. It will also act as a diaphoretic if the body surface be kept warm, while if the surface be kept cool, it will act as a diuretic.

If the urine is nearly suppressed and there are premonitory symptoms of uræmic convulsions, he recommends the use of pilocarpine, which may be given hypodermically or by the mouth. It is a powerful diaphoretic and a useful remedy in urgent cases. The bowels may be acted upon by the use of podophyllin and calomel. Croton oil, one-half or even one drop for a child three or four years of age, he says, will have a marvellous hydragogue effect in cases of uræmic convulsions.

His views are summarized as follows: "Let us not endeavor to break up an attack of scarlet fever, but rather be content with enforcing rigid preventive and hygienic treatment, using mild measures in mild cases; simply controlling the febrile action and temperature; supporting the patient; preventing complications, and curing them when they occur."

In commending these opinions to our readers we do not detract from their worth by pointing out that they differ only in details from those of older writers. Boerhaave, in his 725th aphorism, speaking of scarlet fever (with several other fevers) says: "They seldom require anything more than to keep their matter movable by a sufficiently large quantity of thin or light liquors, and by continually maintaining the *vis vitæ* under its due moderation; for then in a short time they go away with a scaling off of the cuticle." Hippocrates, in his 21st aphorism, says that "One ought not, either by medicines or by any other kind of irritation, to move nor change the matter in those diseases which are near upon or perfectly arrived at a crisis; but that one ought then to do nothing." Sydenham used no medicines in scarlet fever. He did not even always confine his patients to bed. Dr. Mosman, in 1799, found great advantage from sponging the body of scarlet fever patients with cold vinegar and water, using tepid vinegar and water when there was a tendency to chilliness. Dr. Samuel Jackson, of Philadelphia, placed great reliance on the use of ice, kept in the mouth and swallowed, in anginose cases; and Dr. George B. Wood, in 1847, described the treatment of scarlet fever in a manner which could hardly be improved upon.

The reminiscences of the older methods of treating this disease might be continued with interest, but enough has been said, we trust, to direct attention to the sagacity with which our predecessors in the art of medicine exercised their functions, and to the confirmation which their experience affords of the wisdom of such opinions as are expressed by Dr. Waxham, and as are, we believe, shared by all intelligent practitioners of the present day.

SURGERY OF THE BRAIN.

On the subject of the surgery of the brain, no one can speak with more authority, and no one does speak with more convincing force than Mr. Victor Horsley, of London, whose experiments on the lower animals, and whose exceptional experience in operating upon the brain in human beings, entitle his opinion to the highest consideration.

In a paper read before the British Medical Association in 1886, and published in the *British Medical Journal*, October 9, of that year, Mr. Horsley described his method of operating, and illustrated it with accounts of those cases in which he has put it into practice. He has since (in the *British Medical Journal* for April 23, 1887,) written another paper, in which he gives the results of ten cases upon which he has operated for the removal of various lesions of the brain.

Being strongly convinced of the importance of asepsis, Mr. Horsley follows Lister's method, including the spray. The day before operating he has the head of the patient shaved, and washed with soap and ether, and covered with lint soaked in a 1 to 20 solution of carbolic acid, with a dressing of oiled silk and cotton, and gives a purgative, followed by an enema on the morning of the operation.

He prefers chloroform as an anæsthetic, because it causes contraction of the arterioles of the brain, and does not cause the cerebral excitement which often follows the administration of ether. To which we may add that it does not cause vomiting nearly so often as ether does. Before giving chloroform, Mr. Horsley gives one-quarter of a grain of morphia hypodermically — the method of mixed narcosis of Nussbaum. Grave heart disease he regards as a contra-indication to the use of chloroform. He says that cocaine might be used as an anæs-

thetic in such cases, and would have this as aseptic as possible, while he points out the necessity of completely anæsthetizing the dura mater, which is very sensitive, being supplied with nerves from the fifth pair—a fact which seems not to be known to many clinicians.

As to the shape of the operation, Mr. Horsley insists that the old crucial incision should be entirely abandoned in favor of a large flap, and lays stress upon the fact that it must be so outlined as to preserve in its attachment either the superficial, temporal, or occipital artery uninjured. This can be easily done without disfigurement or hindrance to drainage, and at the same time it permits exposure of any portion of the cranium. As regards the reflection of the flap, it has always been the custom to reflect the periosteum as a separate layer. This method has obvious disadvantages, which may be avoided by lifting the whole *en masse*.

Sawing of the bone is most rapidly, and therefore best, accomplished by first taking out an inch disc with a trephine, to learn its thickness, and then by cutting out a piece of the size required with a circular saw, mounted on Bonwill's surgical engine, the separation being completed with very powerful bone forceps. Following McEwen's method in cases where it has been possible to preserve the dura mater, Mr. Horsley replaced fragments of the bone between the same and the skin flap; but although the vitality of the fragments has invariably been perfectly preserved, he had not so far observed much ossification of the cicatrix. This, however, he thinks of little practical importance, since the cavity becomes roofed over with a tough fibrous membrane which well preserves the parts beneath from injury. The dura mater is opened with the scalpel and divided round four-fifths of the opening in the bone, at a distance of one-eighth inch from its edge, so as to admit of its being sutured. The main branches of the meningeal artery are ligated through the dura, before being divided.

Portions of the dura mater which are adherent to tumors are usually very considerably altered. If the mischief has but lately begun, the dura mater will be found highly vascular. In very advanced cases it may be yellowish; and in some instances it is found to be of a dirty reddish color. In all cases where it is adherent, of course the membrane must be freely excised.

Mr. Horsley advises that plenty of brain tissue be removed, especially in the case of new growths. From the experience gained from one of the cases, it is clear that even the most malignant tumors may be successfully attacked, and life thus prolonged and ameliorated. It also shows plainly that malignant growths must be excised very freely from among the white fibres of the brain. In the instance referred to, the recurrence was almost entirely confined to the latter part of the brain.

In the first few cases operated upon, Mr. Horsley employed a drainage-tube in the usual way for the first twenty-four hours, and then left it out. He now sews the wound all round except for one inch at the most dependent part, where any discharge can escape betwen the edges; the object to be attained is immediate union of the flap. As favoring this, Mr. Horsley makes the very important assertion that he believes the arachnoidal, like the peritoneal cavity, may be trusted to absorb excess of fluid.

Mr. Horsley employs strict Listerism, and thinks experience suggests strict attention to details. He has experimentally tested the method of irrigation, to see whether the carbolic spray could be easily dispensed with, and the results of the inquiry have been to convince him that the spray affords the best method of continuously douching the wound with disinfectants. It offers no inconvenience, so far as he can see. All oozing is staunched by gentle pressure with a soft sponge, and the flap is laid down and secured with silk sutures one centimeter apart, with horsehair sutures between them. As to drainage, Mr. Horsley limits this to a period of 24 hours after the operation, after which he removes the drainage tube and endeavors to obtain primary union of the whole wound. After the first four or five days, when the wound is healed, it seems preferable to scatter powdered boracic acid along the dry line of incision, and to fix by collodion a little cotton over all. There is clearly no reason why the original dressing should remain on the head after the wound is sealed and dry.

The only inconvenience, which the patients treated so far have suffered from, has been thirst. Possibly this is in the main due to the morphine. As an additional though minor trouble, the liquid diet of the first three days makes the tongue furred and unpleasant. To remove this, the mouth should be thoroughly brushed several times a day with strong chlorate of potash solution. The patient should be put on solid food as soon as he asks for it. If the case be a comparatively trifling one, he may be allowed to get up at the end of a week. Ten days, however, is a very good average for the stay in bed, and in severe cases a fortnight should be insisted upon.

The details of the cases contained in the the table accompanying Mr. Horsley's last paper, and the experiences of other surgeons, especially in Germany and in America, show that the operation of exposing and removing considerable portions of the brain may be performed in such a way as to render the procedure comparatively safe, and justify the hope that it may prove of great benefit to humanity.

HIGH LICENSE.

The legislature of Pennsylvania, on May 11, passed a high license bill, from which the friends of temperance hope to see many advantages flow. The bill fixes the price for a license to sell liquor at retail at $500.00 a year in the larger cities, and grades it down to $75.00 in townships. One of the best things in the bill is the provision that licenses to sell liquor at retail shall be issued only by the Courts, after an open hearing of the reasons for and against granting a license to a particular person in a particular neighborhood, and that the Court shall in all cases refuse the same whenever, in the opinion of the Court, having due regard to the number and character of the petitioners for and against application, license is not necessary for the accommodation of the public, or the applicant is not a fit person to receive a license. A rather elastic part of the bill provides that the Court shall revoke a license "upon sufficient cause being shown," or upon proof being made that the party holding a license has violated any law of the Commonwealth relating to the sale of liquors.

The readers of the REPORTER will be especially interested to know how the bill deals with the sale and prescription of alcoholic liquors by druggists and physicians. Section 16 provides:

"That druggists and apothecaries shall not be required to obtain license under the provisions of this act, but they shall not sell intoxicating liquors *except upon the written prescription of a regularly registered physician.* Alcohol, however, or any preparations containing the same, may be sold for scientific, mechanical or medicinal purposes. But no spirituous, vinous, malt or brewed liquors shall be sold or furnished to any person more than once on any one prescription of a physician; and any physician who shall willfully prescribe any intoxicating liquor as a beverage to a person of known intemperate habits shall be guilty of a misdemeanor, and upon conviction shall be fined not less than fifty or more than five hundred dollars, and undergo an imprisonment of not less than twenty or more than ninety days."

The provisions of the bill certainly go as far as any one, not a prohibitionist, could reasonably ask; and we hope that they will prove efficient in restricting the promiscuous and irresponsible traffic in intoxicating liquors, which at present is a curse and a disgrace to so many communities.

NOTES AND COMMENTS.

Class Room Notes.

Frrm the excellent "Class Room Notes" in the *College and Clinical Record* for May, 1887, we make the following quotations:

—Prof. Bartholow predicts that when *lobeline* is made in the large quantity, which the demand will no doubt soon necessitate, it will be one of the most used remedies for all respiratory neuroses, generally speaking.

—Prof. Gross advises that a radical cure for a large *hydrocele* should not be undertaken at once. Evacuate its contents, and, when it has again attained a small size, again evacuate and resort to one of the radical means of cure.

—Blisters, cautery, seton, and issue plaster should never be used as a local treatment for *epilepsy.* For any good they may seem to do is only temporary, and the disease will be more aggravated in character when the symptoms reappear.

—Dr. Hunt, at the Pennsylvania Hospital, stated that he considered the treatment of *internal hemorrhoids* by carbolic acid a good procedure. He uses about four drops each of pure carbolic acid and glycerine, and injects one tumor at a time.

—Prof. Gross states that he believes subiodide of bismuth is destined to replace, to a great extent, iodoform in the *antiseptic treatment of wounds.* It is being extensively used at the hospitals, and, as yet, with none but most gratifying results.

—Prof. Parvin states that the best treatment for *chronic mastitis,* if the patient object to the radical operation, is firm compression by means of pressed sponge and a bandage, which is occasionally to be slowly saturated with carbolized water.

—A mixture of collodion 15 parts, corrosive sublimate 1 part, if applied to small, superficial *birth-marks,* is stated by Prof. Gross to act very nicely and effectively.

—Prof. Bartholow recently gave the following as an effective *hair tonic:*

℞ Ext. pilocarp. fluid.,
Tinct. cantharid., āā f℥ss
Glycerini,
Vaselini, āā f℥j.
M. Sig.—Use locally.

—For *ileo-colitis* Prof. Bartholow prescribed as follows:

℞ Ext. ergotæ, gr. j
Ext. nucis vomicæ, gr. ¼
Ext. opii, gr. ⅛
Ft. pil.
Sig.—One every four hours.

—Prof. Parvin states that anteflexion with mobility, in a virgin, is a physiological condition, and can only be called flexion when the uterus becomes immobile and bound down by adhesions.

—For the *irritative fever of consumption*, Prof. Da Costa strongly advises the use of small doses of aconite. He claims it is a remedy of much value, and but little known to the profession in general.

—A case of *sciatica*, following exposure and of nine weeks duration, was treated by Prof. Da Costa in the following manner: Apply a strip of blistering plaster in the course of the nerve, and administer—

℞ Tinct. colchici seminis, gtt. xv
Potassi iodidi, gr. x
Tinct. zingiberis, gtt. x
Syrup.,
Aquæ, āā q. s. ad f℥ij.
M. Sig.—Take with water three times a day between meals.

—Prof. Da Costa recently presented to the class a case of *obstinate vomiting*, which, strange to say, was brought about only by the recumbent posture. Its cause was traced to a chronic constipation, which was treated as follows:

℞ Aloin, gr. 1/12
Strychninæ sulph., gr. 1/60
Extract. colocynth. comp., gr. ½
Extract. hyoscyami, gr. j.
Ft. pil.
M. Sig.—Take after each meal.

A Case of Severe Epistaxis.

Dr. L. Deakley Rood, of Northampton, Mass., reports the following case to the *New York Medical Record:*

"I was called in great haste one evening to see Mr. T., twenty-seven years of age, who, the messenger said, was having a severe hemorrhage. I went at once and found the patient raising great quantities of blood. I at once instituted the ordinary treatment for such cases, and the bleeding was soon controlled. The next morning I saw the patient again. He had been raising some blood, but not very much. The pulse was small, weak, and frequent, and the patient was so prostrated that he could hardly raise his head. I had supposed that the hemorrhage came from the lungs, as all the symptoms pointed that way, but on inquiry I learned that the patient suffered from a chronic nasal catarrh, and that he was unable to distinguish odors—in fact, had never had any sense of smell. The patient recovered his strength quite rapidly, though he still occasionally raised bloody sputa. At the end of a week I made a thorough examination of the throat and nose. The larynx was fairly healthy, but the mucous membrane of the pharynx and nose was badly congested and more or less granular. A day or two later I was called again, as the patient was having another hemorrhage. This was controlled as before, but another and more obstinate attack occurred a few days later. I determined to prevent any further hemorrhage, if possible, as the patient was becoming extremely weak from loss of blood. I therefore applied solid nitrate of silver to the pharynx and nasal cavity, completely covering the mucous membrane. Twelve applications were made, and the patient never had another hemorrhage after the first application. One remarkable feature of the case is that the patient can now smell perfectly, whereas before he was absolutely without the sense of smell. My theory is that the blood ran from the nasal mucous membrane into the pharynx, and made the patient cough, when it was expectorated."

Paris Hospital Therapeutics.

A correspondent of the *Philadelphia Medical Times* gives the following brief glance at the treatment of disease in one of the large hospitals of Paris, presenting as briefly as possible—and yet as completely as possible—the kind of medicinal treatment employed, taking the service of Professor Germain Sée as a guide. The following is from the official book of Salle (or Ward) St. Jeanne, Hôtel Dieu:

Diagnosis.	Treatment.
Anæmia	Hemoglobine and pepsin.
Chlorosis	Sodii arsenias.
Zona	Antipyrine, 4 grammes.
Hemiplegia	Todd's potion.
Peri-uterine phlegmon	Injections, terpine, nux vomica, and gentian.
Syphilis, cerebral	Biniodide of mercury, sulphur baths.
Chlorosis	Ferri et potassii tart., sulphate of aconitine.
Albuminuria	Tannin pill, ergotin pill, terpine pill.
Mitral insufficiency	Sparteine sulph.; convallamarin.

Pericarditis and aortic reg.	Iodide of potash, digitalis, sparteine.
Myocarditis	Caffeine, sparteine.
Thoracic varix	Tinct. hamamelis, antipyrine, Vichy water.
Typhoid fever	Charcoal powder, naphthaline, quinine sulph., rectal injections.
Amyothropsia	Pill opium, mercurial frictions.
Mitral insufficiency	Digitalis infusion.
Dyspepsia	Charcoal powder, benzoate of soda, terpine.
Diabetes	M. Sée's diet, arsenic.
Hydrarthrosis	Antipyrine.
Phthisis	Arsenic, pill opium.
Dilatation stomach	Ipecac powder (5 centigrammes), cocaine hydrochlorate (5 centigrammes); suppress all vegetables.
Not made	Jalap.
Emphysema	Terpine, iodide of potassium, pill opium, sparteine sulphate.

Of course, in this rapid list of actual patients and treatment, we have not time to indicate the symptoms for which some of the remedies were given; but those accustomed to hospital practice will see the reasons, and be able to compare the above with their own practice.

Paraffin in Surgery.

It is, perhaps, not so well known in the profession as it ought to be that paraffin is a most useful material in surgery, in many cases superseding plaster of Paris. It answers admirably for splints and for jackets for young children suffering from spinal disease. The advantages are that it is clean, light, capable of being moulded while it is soft, and sets rapidly by pouring cold water on it. It must be procured with a melting point of 130°. When ordering it, it is necessary to specify the melting point required. The mode of using it is this: The paraffin is melted by placing a tin can containing it in a pot of boiling water. A muslin bandage well sprinkled with iodoform is put on the limb or other part to which the paraffin dressing is to be applied. Muslin bandages, loosely rolled, are allowed to soak in the paraffin for a few minutes. If much support is required, a piece of cotton-wool is also soaked in the paraffin. This is placed where most stiffness is wanted, and the bandage applied as for plaster of Paris dressing. It may, however, be drawn tight, as the paraffin shrinks from the limb in cooling. Cold water is then poured on it, and the limb is held in position till the paraffin has set. When a bone tends to project, it can be kept in position by the finger till the paraffin has set. The hole left by the finger can then be filled up with some melted paraffin. In cases of compound fracture, the paraffin has the great advantage of not being affected by the discharge from the wound.—*Albany Medical Annals.*

The Flax-seed Fallacy.

Dr. Williams, in the *St. Louis Medical Journal*, says: If we were to ask every man and woman in almost any community what is the best way to get any foreign substance out of the eye, probably fully one-half those questioned would say, "Put a flax-seed into the eye—it's a sure cure!" Every few days some one who has followed this advice comes to me for relief. Only a day or two ago a young man, with an eye full of flax-seed, came to me, stating that the seed had been in the organ all night, and that he could not sleep, because all night long *he could feel the seed chasing the foreign substance around and around under the lid*, but for some strange reason the substance "could not be forced out!" I have never seen any account of the origin of this superstition—for it is nothing more—but it is probably very ancient. Unlike most ancient superstitions of this sort, it has absolutely no foundation in fact. Any one who has a foreign substance in the eye, and sends a flax-seed to "chase it out," simply adds fuel to the flame. It is fortunate that the seeds are smooth and comparatively unirritating, as otherwise the fallacy would be a more serious one. Another and similar superstition is that foreign matters may be chased out by a "stone from a crab's eye"—which is nothing more nor less than the crystalline lens of the eye of the crustacean, hardened by boiling.

Iodoform in Venereal Diseases.

A review of the literature of the subject, joined to his own experience with iodoform in venereal diseases, has led Dr. Bockhart to formulate the following aphorisms:

Iodoform is not of the least use in the treatment of gonorrhœal inflammation.

Ulcers and erosions of the vaginal portion of the uterus, the result of cervical gonorrhœa, are amenable to iodoform.

Iodoform should be regarded as a specific against the virus of soft chancre, and is the best, surest, and most rapid means of treating all sorts of soft chancres.

Suppurating inguinal buboes are best and most surely treated with iodoform, especially after the method of Petersen.

In syphilis the internal use of iodoform is far less satisfactory in its results than that of iodide of potassium, and it is most useful in syphilitic neuralgia.

Iodoform is of use in treating the ulcerated gumma of syphilis, alone of all its lesions. Upon this it seems to exercise a specific action.—*Medical Summary.*

Benzoin in Treatment of Ulcers.

In a recent number of the *Russkaia Meditzina*, Dr. A. Voskresensky, surgeon to the Fëodosïïsky Regiment, speaks highly of benzoin as a specific for ulcers, especially those which occur in emaciated, cachectic, and old persons. The remedy has been largely used for the purpose by Russian peasants from time immemorial, after a crude fashion. The author employs it in shape of a salve, prepared *extempore*, of two drachms of resin benzoin, half an ounce of yellow wax, and half an ounce of lard. The ointment is spread in a moderately thick layer over a piece of linen, and placed on the ulcer. The latter must be previously irrigated with tepid water, and then dried with hygroscopic cotton-wool. The dressing is to be changed as a rule twice daily, but in cases of very large or old ulcers it is advisable to change it three times a day. A marked improvement becomes visible within a few days; torpidity of the ulcer, callosity of its edges, and its liability to bleed rapidly disappear; granulations assume a more rosy tint, and begin to discharge a thick benign pus; while there appears a whitish-bluish zone of corium, which gradually spreads from the periphery towards the centre of the ulcer. This favorable action of benzoin on ulcers is ascribed by the author partly to its disinfectant and antifermentative properties, and partly to irritation.

Treatment of Typhoid Fever at Roosevelt Hospital.

Dr. Asta-Buruaga reports in the *New York Medical Journal* of April 30, 1887, the treatment of 45 cases of typhoid fever in this hospital as follows:

The treatment was mainly expectant. Equal parts of milk and lime-water constituted the sole diet as long as the fever lasted. Forty grains each of subnitrate of bismuth and pepsin, divided into four doses, were given in the milk daily. Stimulants in the shape of whiskey were ordered according to requirements.

The convalescents were allowed solid food, commencing with tenderloin steak on the tenth to the twelfth day after the subsidence of the fever, and were generally allowed to sit up about five days later.

Small doses of Fowler's solution of arsenic were given with good results, when the fever was protracted.

Antipyretics were required in several cases. Antipyrine, antifebrine, the cold pack, the cold bath, and the abdominal water-coil were used.

The mortality was 8.88 per cent.

Good Advice.

Dr. Buller, in a farewell address to the graduates in Medicine of McGill University, on March 29, 1887, held up before his hearers an admirable picture of the spirit which should animate the true physician, and illustrated it by reference to the lives and sayings of eminent men in the profession. He quoted Sydenham as saying: "My fame is in the hands of others. I have weighed in a nice and scrupulous balance whether it is better to serve men or to be praised by them. I prefer the former. It does more to tranquillize the mind; whereas fame and the breath of popular applause is but a feather, a bubble, and a dream. Such wealth as fame gives, those who have scraped it together and those who value it highly are fully free to enjoy; only let them remember that the mechanical arts (and sometimes the meanest of them) bring greater gains and make richer heirs." He also said: "A hundred and fifty years ago William Cullen gave advice to a young man just starting out in life which any young man would do well to take heed of to-day. He says: 'Study your trade eagerly, decline no labor, recommend yourself by briskness and diligence, bear hardships with patience and resolution, be obliging to everybody, whether above or below you, and hold up your head both in a literal and figurative sense.'"

Pruritus Ani.

This troublesome affection has been found by Bangs (*N. Y. Med. Month.*) to be due in some cases to irritation of the genital organs, as by stricture of the urethra, or by acute or chronic enlargement of the prostate, and he has succeeded in curing the pruritus by curing the source of irritation. In one case occurring with acute prostatitis, the intense itching was cured by hot-water rectal injections. In another case of intense pruritus which had resisted all attempts at relief, a very sensitive condition of the urethra was found, dependent upon prolonged sexual intercourse. The patient was cured by the passage of a sound, and by correcting his bad sexual habit. Sev-

eral other interesting cases are reported, all illustrating the connection in some cases between the itching of the skin and irritation in the genital tract.

Cost of an Electro-Therapeutic Outfit.

Dr. Wm. F. Hutchinson, in the *Medical Register* of May 11, 1887, states that with the following supply of instruments the doctor will be ready for any emergency in which electricity can be used in medicine. There will, of course, come times when a special appliance will be needed; but stout brass wire, a pair of cutting pliers, and a little ingenuity, will readily supply such need. Let us recapitulate the outfit and see how much all this is going to cost in round numbers:

One galvanic battery, portable	$35 00
One galvanic battery, office	35 00
One Faradic machine	30 00
Eight galvanic electrodes with handles.	15 00
Six sponges and holders	6 00
One wire brush	1 50
One eye cup	1 50
Or a total of, say, ...	$114 00

From this there will be some trade discount, probably enough to reduce the amount to $100, net.

The Effect of Cobra Poison.

According to *Nature*, the taxidermist of a Ceylon museum received a bite from a cobra whose fangs had been removed, and which was consequently supposed to be harmless. Pain and nausea ensued, and the man soon ceased to breathe. Artifical respiration was kept up for *nine hours*, when he improved. He stated that he had been conscious all the time, but was unable to make his feelings known, not having power over a single muscle. He could hear and see, but there was no response when his eyeball was touched. The poison thus appeared to be a motor paralyzant. Unfortunately, although he recovered full consciousness, he died five days after the bite. The similarity of the poison in this case to curare is at once apparent.

Aconite in Neuralgia.

Dr. A. Dumas, surgeon to the Hospital of Cette, gives the following indications for the use of this medicine:

"Aconite is an energetic, very efficacious remedy, especially in congestive facial neuralgia, and in some other kinds of neuralgia *a frigore*. It is useful in catarrhal affections in general. Like other alkaloids, there is a certain degree of tolerance of it, when methodically administered, and no effects of accumulation in the organism are apt to be apprehended. It is better to give it in very divided doses, and at carefully calculated intervals. One ought to begin with small doses, which are progressively increased."—*New England Med. Monthly.*

Nettle Juice.

Les Nouveaux Rémèdes states that the best remedy for hemorrhages of all kinds is nettle juice. It is better than tannin, chloride of iron, sulphuric acid, hydrochloric acid, or ergot. The illustrious Chomel said: "This remedy is the most certain to stop hemoptysis and all hemorrhages."

The difficulty heretofore has been that the remedy was not available, because it will not keep. However, a pharmacist, M. Peneau, has conceived the happy idea of preparing a syrup from the juice. This is done at a time when the plant is in full vigor. In this form the medicine does not alter. and keeps indefinitely.—*Nat. Druggist.*

Turpentine in Impetigo.

Dr. Saerbs recommends essence of turpentine as a local application in impetigo of the scalp or other hairy parts. The preparation should be well rubbed into the skin and roots of the hair with the fingers. After about five minutes it should be washed off with carbolic soap and afterwards with warm water. Tincture of iodine should be next applied. This treatment should be carried out once or twice a day; it causes slight itching. but is not painful. The author has found it successful where other modes of treatment have failed.

Confirmation Precedes Credence.

A physician living on the seaboard, thus writes: "Within the last five years, in a district embracing sixty square miles or so, by the sea, I have noted the hour and the minute of no less than ninety-three demises in my own immediate practice, and every soul of them has always gone out with the tide, save four who died suddenly by accident. It is a riddle—a mystery. But I, who have sat with my fingers on the wrist of many a feeble patient, and noticed the pulse rise and strengthen, or sink and vanish, with the turning of the tide, know that it is a fact."

Substitute for Court-Plaster.

The *London Medical Record* contains the following formula, which has been used to

prepare a calming and adhesive preparation, suitable for neuralgias, or tender, inflamed, or abraded surfaces. Pieces of linen or silk dipped into it answer the same purpose as the so-called "court-plaster:"

℞.	Mastic,	℥iij.
	Balsam Peru,	℥j.
	Narcotine,	℥j.
	Chloroform,	f℥vj.

The first three substances must be powdered separately, and then added to the chloroform.

A Disinfectant.

A new disinfecting compound for purifying the atmosphere of a sick-room has just been presented to the Berlin Medical Society. A mixture of the oils of rosemary, lavender, and thyme, in the proportions of 10, 2½, and 2½ parts, respectively, is combined with nitric acid in theproportion of 30 to 1½. The bottle should be shaken before using, and a sponge saturated with the compound and left to diffuse by evaporation. Simple as it is, the vapor of this compound is said to possess extraordinary properties in controlling the odors and effluvia of offensive and infectious disorders.

Rupture of the Bladder.

Rupture of the bladder may be definitely diagnosticated without laparotomy in the following manner: Introduce first into the rectum a Petersen's rubber bag, and distend with water, not exceeding eight ounces; next, inject through a soft catheter into the bladder, not exceeding eight ounces of warm antiseptic fluid (1 per cent. carbolic solution), note the upper line of supra-pubic dullness, withdraw the fluid from bladder, and measure. If there is *no rupture*, the fluid will measure the same as that injected.—*Weir, in Medical Record.*

Mixture of Oil of Wintergreen.

Much difficulty has been reported in finding an eligible mixture containing oil of wintergreen, so valuable in acute rheumatism, and also employed in other affections. The following may be commended:

℞.—Olei gaultheriæ,		♏clx.
Mucilag. acaciæ,		f℥ij.
Glycerinæ,		
Aquæ,	āā	f℥j.

M. Sig.—Dose, one to two teaspoonfuls, as may be required.

Bronchitis.

The following formula of Dr. Horatio C. Wood appears in the *Union Médicale du Canada:*

℞.	Kalii citratis,	15 parts.
	Lemon juice,	30 parts.
	Syrupi ipecac.,	15 parts.
	Syrupi simpl.,	90 parts.

Mix. One teaspoonful for a dose every two hours.

Freshly-prepared citrate of ammonia, with the addition of small doses of ipecac wine, was a favorite bronchitic remedy of the late Sir P. Crampton.

Styes.

Styes are such troublesome little ailments, that the following remedy for their cure recommended by M. Abadie, may be welcome:

℞.	Acidi boracicis,	10 parts.
	Aquæ dest.,	300 parts.

Dissolve.

With a wetted piece of wadding drop some of this solution on the stye several times a day. It is said not only to effect a cure, but to prevent a return of the annoyance.—*Medical Press and Circular, April* 20, 1887.

Treatment of Ivy Poisoning.

Dr. H. Hahn writes to the *Therapeutic Gazette* that the following prescription has given him good results in the treatment of the dermatitis caused by rhus toxicodendron:

℞.	Acid. carbolic.,	℥j.
	Liq. ammon. caust.,	℥ss.
	Ol. olivæ,	℥iij.

M. Sig.—Compresses to be moistened and applied once in two hours to the affected parts. If the eruption be very acute and painful, cover the compresses with an ice-bag.—*Practitioner and News.*

Instantaneous Remedy for Lumbago.

The following mixture can be employed in cases of accidental lumbago, or rheumatic pain produced by strain or muscular exertion:

℞.	Collodion,	
	Tr. iodini,	
	Aquæ ammoniæ,	āā f℥j.

M. Sig.—Apply freely and widely over the affected parts with a camel's hair brush.—*K. C. Medical Index.*

An Anodyne for Dental Caries.

The following mixture is recommended:

℞.	Camphor,	5 parts.
	Chloral hydrate,	5 parts.
	Cocaine hydrochlorate,	1 part.

On heating this mixture to the boiling point of water, an oily liquid is formed.

This is to be applied lightly, and it is said that after a few applications the pain will surely be alleviated.—*Physician and Surgeon.*

Antiseptic Mouth Wash.

℞. Sodæ biboratis, 1 patt.
Thymol, ½ part.
Aqua destill., 300 parts.
Ft. sol.

This preparation is said to be an excellent corrective for fetid breath, when it proceeds from decaying matter in carious teeth, etc. —*Magitot, in Gazette Hebdomadaire.*

Treatment of Cystitis and Genito-urinary Hyperæsthesia.

℞. Ext. Pichi (Fabiana Imbricata), f℥vj.
Liq. potass., f℥ss.
Elix. arom. q. s., f℥iij.
M. S.—Ten drops to a teaspoonful every three hours.

Remarkable improvement follows within twenty-four hours.—*Cal. Med. Journal.*

Obstinate Chlorosis.

Obstinate chlorosis attacks all young girls, without exception, in whom the menses have appeared in the twelfth or thirteenth year, and before the development of the breasts and pubes.—*Niemeyer.*

News and Miscellany.

Camden County Medical Society.

The annual meeting of the Camden County Medical Society was held at the Buena Vista Hotel, Gloucester City, recently. Dr. John R. Stevenson read a paper on the water supply of Camden, Gloucester and Haddonfield, and the county streams.

Dr. J. W. Snowden presented a report on the prevaling diseases of the county during the year. Measles, scarlet fever, diphtheria and chicken-pox were reported as the most prevalent.

The election of Dr. James A. Wamsley as a member of the Society was confirmed, and the following physicians were elected to membership: W. H. Jones, Alexander McAllister, R. G. Taylor and William Schaeffer, of Camden, and J. J. Glover and W. S. Long, of Haddonfield. Dr. H. Genét Taylor resigned from the Secretaryship of the Society after a service of twenty-five years. A committee was appointed to draft suitable resolutions. The following officers and delegates were elected:

President—Onan B. Gross.
Vice-President—W. H. Iszard.
Secretary—E. L. B. Godfrey.
Treasurer—Alexander Mecray.
Board of Censors—H. G. Taylor, J. R. Stevenson, H. E. Branin, Alexander Marcy and J. W. Snowden.
Standing Committee — Drs. Townsend, Shivers, Bronin, Smith and Dobson.
Nominating Committee — Drs. Pancoast, Blake and Bronin.
Delegates to American Medical Association —Drs. Dobson, W. A. Davis, Godfrey, Snowden, Gross and H. G. Taylor.
Delegates to New Jersey State Medical Society—Drs. Ridge, Hoell, Donges, H. H. Davis, Godfrey and Smith.
Delegates to Burlington County Medica Society—Drs. Townsend and Robinson.
Delegates to Cumberland County Medical Society—Drs. Pancoast, Schellinger and J. W. Wiels.
Delegates to Gloucester County Medical Society—Drs. Hurff, Woolston and Tomlinson.
Delegates to Ocean County Medical Society —Drs. Benjamin and Haney.
Committee of Arrangements—Drs. H. G. Taylor, Godfrey and White.

Medical Competition in New York.

"Here in New York very little surgery falls into the hands of the young practitioner. Most of the surgical cases occur among the laboring classes, and the ambulance carries them off to the hospital, where they are welcomed. The wealthier patients can afford to employ surgeons of established reputation, and consequently, however well prepared a young doctor may be to treat broken limbs, even after a thorough hospital training, his chances for showing what he can do will be very slim. In many parts of the city, doctors are so numerous that the rivalry leads to a reduction of fees. Doctors living near tenement districts are expected to make visits, including long distances and climbing to the tops of five-story houses, for $1.00. Occasionally I have had doctors tell me of patients making an office visit and expecting only to pay fifty cents, saying that Doctor So-and-so (a good man) only charged half a dollar in the office. The only reply to such remarks is that Doctor So-and-so probably knows the value of his services. There are many amusing stories told of the means resorted to sometimes for getting patients. A doctor living on a block where physicians are numerous, recently told me

the following: "A patient of his called at the office one evening, and was informed on the stoop by the servant that the doctor was not at home. The patient descended the stoop, and while passing the next house a voice from the window said: You will find just as good a doctor in here, sir. The man thanked his unseen informer, but said he thought not. Unless there are some special reasons for young physicians locating in New York, they will certainly do better elsewhere."—*N. Y. Correspondent of Atlanta Med. and Surg. Journal.*

A Prize Essay on Hay-fever.

At its last meeting, September, 1886, at Bethlehem, New Hampshire, the United States Hay-Fever Association decided to offer a prize for the best essay from a competent source, preferably a physician, on some question relating to *Catarrhus æstivus*, or hay-fever.

In order to carry out the above, the following is announced officially:

1. Subject of the Essay: Hay-fever. (*a*) Its pathology. (*b*) The predisposing and the aggravating causes. (*c*) Advice to the sufferer.

2. The essay not to exceed *four thousand words*, and to be as practical and non-technical as possible.

3. The manuscripts to be received at the office of Samuel Lockwood, Freehold, New Jersey, not later than April 30, 1887.

4. Each manuscript to have a motto under the title, and to be accompanied by a sealed letter containing said motto, also the name and address of the author. These letters not to be opened until after the award is decided.

5. The prize to be $25. The accepted essay to be published immediately in the Association's annual report, one hundred copies to be given the author.

6. The committee of award: Samuel Lockwood, Chairman of Committee on Scientific Facts; Frank B. Fay, President U. S. H. F. A.; Charles C. Dawson, Secretary U. S. H. F. A. SAMUEL LOCKWOOD,

Chairman of Committee on Scientific Facts.
Freehold, N. J., January 15, 1887.

Snap Diagnosis.

Daniel's *Texas Medical Journal* tells the following true story of a Texas physician who makes a "snap diagnosis:" "He was consulted by the wife of an influential citizen, who said: 'Doctor, my baby is strangely affected, and I want you to tell me what's the matter. Whenever it goes to make water it seems to suffer great pain, and almost goes into convulsions.' 'Why, my dear madam,' replied the doctor, with the pompous and confident air of one who saw his opportunity for a brilliant hit, 'it is a clear case of elongated, and perhaps adherent prepuce.' 'Ah! indeed,' said the lady; 'and you are *sure*, doctor, that is what ails it?' 'Perfectly sure, madam; couldn't be mistaken; had thousands of such cases.' 'And what can you do to relieve it, doctor?' 'Oh, simple enough, my dear madam,' said the doctor, 'I'll just remove the surplus preputial tissue, stitch the integument and mucous membrane back with a couple of antiseptic sutures, and the little fellow will be all right.' 'But,' said the lady, with a mischievous twinkle in her eye, 'doctor, my baby is a girl!' Exit the doctor, who had a patient to see just about that time. Fact."

Chloral in Labor.

A correspondent of the *Medical Age* says: For a great many years I have been using hydrate of chloral in cases of labor, with remarkable results. When I am called to attend a woman in labor, and find the os undilated or rigid, I invariably inject into the rectum 30 grains of hydrate of chloral dissolved in about four ounces of warm water, with a little starch added. I have used this means for such cases for eight years, and have failed to get any but the most flattering results; in fact, I can not prize the method too highly. On the 28th of this month I was called to a case of placenta prævia; the woman had been flowing all night, and when I got there, at 6 o'clock, a m., she had lost much blood. I found the os rigid and undilated. I immediately injected my favorite remedy, and in less than three minutes the os was dilated so that I could readily pass my hand into the uterus, and the rectum, vagina and perineum were well relaxed. The drug has never failed me yet in this connection, and I would like to commend it to others who may not have used it.

To Err is Human.

A correspondent writing to the *Cleveland Medical Gazette* says: "Billroth is a marvelous surgeon—operates like a god—with an elegance and certainty with which only Billroth can operate. But he is a very poor speaker, and it is extremely difficult to understand him. I saw an incident which I think will interest you. A patient was brought before

Billroth with a swelling in the perinæum. I thought of several things that it might be, and before I was aware of it, Billroth commenced to lecture on the subject of hernia. For heaven's sake, what had this to do with hernia? But I was soon to find out. In the course of his elaborate lecture, he suddenly launched upon ischiatic hernia. Now I saw the connection, and I thought: 'This is the place to see rare things.' Well, after he had finished the patient was narcotized. The initial incision was made with Billrothian elegance and grace. Lo and behold! in the depth sat a beautiful, round, circumscribed and yellow lipoma. We are not infallible, Billroth included."

The Bureau of General Information.

Office in the Corcoran Building (opposite the Treasury).
WASHINGTON, D. C.,

EDS. MED. AND SURG. REPORTER:

GENTLEMEN: The library of the Surgeon General's office, as you are doubtless aware, is the most complete medical library, with the best subject index, in the world.

Hitherto physicians have not always been able to obtain reports of cases, or other references, from this source of information, because they have not known of any one upon whom they could rely to go to the library, examine the subject catalogues and supplementary indices, find the required references, and make the necessary transcripts.

This bureau has performed these services for physicians and medical authors, and is prepared to attend promptly to any such work that may be ordered. Terms, $1.00 an hour for research; 10 cents a folio for type-writer transcripts, and 30 cents a folio for translations.

Very respectfully,
JOSEPH B. MARVIN,
P. O. Lock Box 379. *Manager.*

The Prehistoric Syringe.

In certain countries there are found calabashes much attenuated at one extremity. These are emptied and a large opening made in the body of the gourd; another opening is made in the neck. Here we have a syringe. The medicated mixture is poured into the calabash syringe, with the neck previously adjusted. To administer an injection, the operator applies his mouth to the large opening and forcibly projects the mixture into the intestine of the patient. If we judge of the habits of prehistoric times by those of present savage races, we have here a prehistoric syringe, which has been perfected through the ages, becoming later on a bladder to which was affixed a nozzle, which we see still in use by veterinarians in the country, and which served our ancestors before the fifteenth century, that memorable epoch when Marcus Gatenaria invented the syringe with a piston.

How to Cut a Bottle.

A correspondent of the *Chemist and Druggist*, in describing how to make a percolator, mentions the following method of cutting a bottle: "I was first shown how to do it by an ingenious mechanic, and have since seen the same published in Spons' "Workshop Receipts." Put the bottle on a level foundation and fill up with oil (I use linseed oil, being able to use it in paint-making afterwards) as far as you wish the line of separation to be. Next get a rod of iron as large as possible, but small enough to go into the mouth of the bottle. Make the iron almost white hot and dip into the oil. In a very short time a crack will be heard, when the iron can be taken out, and the bottle will be found as neatly cut as if with a diamond. Should the bottle be very thick, and the crack not heard in a minute or so, a dash of cold water outside will settle the business."

A Sensible Suggestion.

Dr. Morris, of New York, speaks as follows in *Progress* for April: If one surgeon in every large town would devote enough time to the special study of malignant tumors, he would be surprised at the number of patients who would go to him—provided that he said things to each patient which would prove to be approximately correct. These patients now slip off quietly to some "cancer doctor" at a distance, and the medical men of the town do not hear of the cases being treated at all, or the patients conceal the true nature of their complaints and pass away, having received nothing more than household treatment. I would not have it understood that I should like to see a cancer *specialist* in every large town—or any where else, for that matter—for nothing cramps a good mind more surely than devotion to a small specialty.

Scientific Medicine and Christianity.

Rev. A. P. Happer, M. D., in an address to medical students in New York city, said: "In the providence of God, the knowledge of *scientific* medicine and surgery *only exist*

in countries *where Christianity is found.* It is safe to say that the knowledge of healing is thus, in the providence of God, given in connection with Christianity, and is therefore as sacred a trust on the part of those who have it, as Christianity itself. * * * You may search from China to India, and every heathen and Moslem country, and the result of your investigation will soon confirm this position, that in no heathen or Moslem country is there an instance of the existence of any *scientific medicine or surgery.*"—*Med. Miss. Rec., January,* 1887.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS.

In the Medical Corps of the Navy, for the week ending May 14, 1887:

Surgeon C. U. Gravath, detached from the U. S. S. Michigan.

Passed Assistant Surgeon G. P. Lumsden, ordered to the U. S. S. Michigan.

Passed Assistant Surgeon Richard Ashbridge, detached from the Naval Academy, and to the practice ship Constellation.

Passed Assistant Surgeon Thos. H. Streets, promoted to surgeon.

U. S. Marine Hospital Service, for the week ended May 14, 1887:

Fessenden, C. S. D., surgeon. Detailed as chairman of Board for physical examination of cadets, Revenue Marine Service, May 13, 1887.

Stoner, G. W., surgeon. To proceed to Delaware Breakwater as inspector, and to New York and Philadelphia, to inspect unserviceable property, May 12, 1887.

Irwin, Fairfax, passed assistant surgeon. Detailed as recorder of Board for physical examination of cadets, Revenue Marine Service, May 13, 1887.

Fattic, J. B., assistant surgeon. Relieved from duty at Baltimore, Md.; ordered to Marine Hospital, St. Louis, Mo., May 13, 1887.

The Cartwright Prize.

At the Commencement of the New York College of Physicians and Surgeons, held on May 12th, the Cartwright Prize of $500 was awarded to Dr. B. F. Curtis, of New York, for his essay on Injuries to the Abdomen and Rupture of the Intestines. The Prize Committee also made honorable mention of the essay of Dr. H. A. Hare, of Philadelphia, on the Action of Antifebrin, Salicylic Acid, and Carbolic Acid on Normal and Abnormal Bodily Temperature. Dr. Smith, of New York, also received honorable mention for his essay.

Masterly Inactivity.

"It is a part of the biography of Majendie, that when young practitioners would in their ardor vaunt the success of remedies, he would smile and reply to them with pleasant irony, 'It is plain to be seen, young man, that you have never tried the plan of doing nothing.' Learn old Majendie's lesson, carry it with you into your sick room, and when in the blindness of ignorance you can do naught but err, do nothing—do nothing."—*Dr. Erskine, in Miss. Valley Med. Monthly.*

An International Congress of Inebriety

Is to be held in London on the 5th and 6th of July, under the presidency of Dr. Norman Kerr. Among the American gentlemen whose names are included in the list of vice-presidents are Dr. T. D. Crothers, Dr. N. S. Davis, Dr. J. H. Blanchard, Dr. L. D. Mason, Dr. C. H. Hughes, Dr. J. B. Mattison, Dr. Joseph Parrish, Dr. T. L. Wright, Dr. E. C. Mann, and Dr. Albert Day. Dr. Crothers is chairman of the American committee.

A New Museum of Hygiene in Berlin.

A large hygienic museum has recently been opened in Berlin. The rooms on the first floor, of which there are sixteen, contain exhibits relating to fire, building, heating, ventilation, lighting, water-supply, and road and street making. On the second floor are eighteen rooms, in which are shown objects used in civil and military nursing, clothing, baths, education, asylums, prisons, etc.

Love Among the Elements.

Potassium stole from her napthalin cell,
And roaming around fell into a well;
When Oxygen, prince of the air and water,
Caught full in his arms the cloister's fair daughter.
With ardent delight she returned his embrace,
And flung the gray veil from her beautiful face;
When Hydrogen, smarting with true wifely shame,
Went off in a huff, her cheeks all aflame.

Prize of $1000.

The Concentrated Produce Company, of London, offers the above prize for the best work upon the "Physiological Action of the Narcotic Principle of Hops." Competition is open until February, 1888.

Items.

—Dr. Brown-Séquard has just been elected President of the Société de Biologie, to serve for five years.

—The mortality from labor in China is estimated to be eight per cent., or about four hundred thousand deaths annually.

—A State Board of Health has just been organized in Vermont, making twenty-nine States which now have State Boards.

—Charles Reade, the novelist, was credited with having named a dog Tonic, because it was a mixture of bark, steal, and whine.

—The Missouri Legislature has passed a bill making it a felony for a physician to prescribe liquor except in cases of actual sickness.

—The sixth German Surgical Congress, which met last month at Berlin, elected Volkmann President, Bergmann Vice-President, and Billroth and Spencer Wells honorary members.

—Gautier has discovered six bases of a non-poisonous character in meat extract. It seems probable that poisonous bases are formed by bacterial action upon the non-poisonous ones.

—Following the lead of Denmark, the government of the Canton de Vaud, Switzerland, has absolutely forbidden public exhibitions of the phenomena of hypnotism, animal magnetism and somnambulism.

—The announcement is made in *Vratsch* and other medical journals that all foreign physicians resident in Russia, but especially those from Austro-Hungary, must become naturalized immediately or get out of the country.

—The Senate of Connecticut has passed a bill prohibiting post-mortem examinations of persons dying in hospitals unless the relatives are willing, and death was not the result of a criminal act, omission or neglect of some person.

—It is an interesting fact noted by the *Med. Press* that Dr. Grawitz, assistant to Prof. Virchow, has found that in as many as one-third of the cases of so-called muscular rheumatism which have been examined post-mortem, the presence of the trichina spiralis has been demonstrated.

—The ordinary drink of the people in China is boiled water in the shape of a hot infusion of tea leaves. Reflecting on this subject, Mathieu Williams remarks that the Celestial empire could never have reached its present density of population were Chinamen in the habit of drinking the water of their extremely polluted rivers and water-courses raw instead of cooked.

—Dujardin-Beaumetz says: "I can assure you that, the older I grow, the more chary I become in the use of morphine; for despite the marvellous properties of this alkaloid, which is by far the most active of analgesics, its dangers and disadvantages are such that I reserve its employment for exceptional cases."

—The disinfecting institution in Berlin has disinfected during the past six weeks not less than 982 mattresses, 70 straw beds, 1,504 feather beds, 4,437 shirts, 1,229 parts of dress, 2,340 pieces of carpets and curtains, 74 sofas and chairs. The income ($400) hardly paid the expenditures. The disinfection (by superheated steam) was chiefly done in cases of diphtheria and scarlet fever.

—Doctor's office, St. Louis. Enter a lady with a sick dog. "My dear Dr. ——, you must not be angry with me, but won't you please cut off this tumor on poor Fannie's flank?" "Well, madam, I would do anything to oblige you, but this is a little out of my line. Why don't you take the dog to a veterinary surgeon?" "But, doctor, those veterinaries are so expensive. I supposed you could do it just as well."—*St. Louis Republican.*

—From data furnished by over 6,000 cases in a table prepared by Ansell, and from similar results in other tables, Dr. J. Matthews Duncan concludes that married women, who do not become pregnant within six months after marriage, already exhibit a degree of relative sterility; and that when a married woman remains until the end of the fourth year without conceiving, the probabilities are strong that she will prove absolutely sterile.

—The increasing number of medical men to be found among literary people of late years shows that many physicians are desirous of the fame which Dr. Locke attained by his essay, which Dr. Oliver Goldsmith reaped from the "Deserted Village," which Dr. Erasmus Darwin gained from the "Botanic Garden," which rewarded Dr. E. A. Poe for the "Raven," and which repaid Dr. Holmes for his "Autocrat of the Breakfast Table." Sir Henry Thompson, of London; Dr. S. Weir Mitchell, of Philadelphia; Dr. W. A. Hammond, of New York; Dr. Donaldson, of Baltimore; and Dr. John Godfrey, of Indianapolis, are all reaping laurels in the field of romance.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

GREEN SPRING SANITARIUM,
AND
WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten aces. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and massage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

BELLEVUE HOSPITAL MEDICAL COLLEGE,
CITY OF NEW YORK.

SESSIONS OF 1887-88.

The REGULAR SESSION begins on Wednesday, September 21, 1887, and ends about the middle of March, 1888. During this Session, in addition to the regular didactic lectures, two or three hours are daily allotted to clinical instruction. Attendance upon at least two regular courses of lectures is required for graduation.

The SPRING SESSION consists of recitations, clinical lectures and exercises, and didactic lectures on special subjects. This Session begins about the middle of March and continues until the middle of June. During this Session, daily recitations in all the departments are held by a corps of Examiners appointed by the Faculty.

The CARNEGIE LABORATORY is open during the collegiate year, for instruction in microscopical examinations of urine, practical demonstrations in medical and surgical pathology, and lessons in normal histology and pathology, including bacteriology.

For the annual Circular and Catalogue, giving requirements for graduation and other information, address Prof. AUSTIN FLINT, Secretary, Bellevue Hospital Medical College, foot of East 26th Street, New York City.

ARTIFICIAL SULPHUR WATER, AS A SUBSTITUTE FOR BERGEON'S TREATMENT OF PHTHISIS.

BY H. C. WOOD, M. D., LL. D.,

Professor of Therapeutics and Diseases of Nervous System, University of Pennsylvania.

Almost from time immemorial, waters of various sulphur springs have been used in the treatment of disease with more or less pronounced advantage. It is indeed notorious that many cases which have failed to yield to the most skilful home treatment have more or less imperfectly recovered at such springs. Experience has shown that especially three classes of cases are benefited. First, all forms of chronic gout; second, various forms of mucous catarrhs, including some cases of so-called consumption; third, skin diseases.

It will be remembered that when Bergeon inaugurated the system of rectal injections which has created so much excitement in the treatment of phthisis, the main agent which he employed was natural sulphur water. The carbonic acid bubbling through this carried over with it an uncertain amount of sulphuretted hydrogen, which was undoubtedly the active agent. Both in France and in this country artificial solutions have been substituted with advantage for the natural sulphur waters used by Bergeon, such artifical solutions yielding the sulphuretted hydrogen more freely than did the natural waters. I think it may be considered as established, that in many cases of consumption Bergeon's treatment has yielded very extraordinary results. That these results are not achieved by any specific action upon the tubercle bacillus is shown by the fact that the bacillus does not disappear from the sputa, and especially by the fact that bronchorrhœa and other pulmonic catarrhs not dependent upon the presence of the tubercle bacillus, are affected even more pronouncedly for good by the sulphuretted hydrogen than are the cases of true phthisis. It would seem, indeed, that the experience with the Bergeon's method is precisely in accord with that obtained at the various sulphur springs, namely, that sulphuretted hydrogen is a valuable remedy in the treatment of pulmonic catarrhs. The disadvantage of the Bergeon's method is the cost of the apparatus, the time and assistance required for the administration of the injection and the colicky pains which are not rarely produced. The advantages of the method over the administration of the gas by the mouth are not clear. It is simply absurd to suppose that it can make any difference in the action of sulphuretted hydrogen upon the general system or the pulmonic mucous membrane, whether it is absorbed, through the colon or through the small intestine. In either case the gas, as soon as absorbed, enters the portal circulation and passes by exactly the same route to the lungs. A further objection which might well be urged against the rectal administration is the impossibility of judging of the amount of sulphuretted hydrogen which is introduced into the bowels.

If a natural sulphur water is employed, the gas must vary indefinitely, and always be in very small amount in proportion to the carbonic acid. When an artificial solution is used, and the production of sulphuretted

hydrogen depends upon the reaction between the carbonic acid gas and certain ingredients in the solution, more of the gas enters the patient, but the amount is still uncertain. The activity of chemical reactions notoriously varies with the temperature of solutions and with other circumstances still less readily controlled. Led by these considerations, I, some weeks ago, commenced the administration of sulphuretted hydrogen water by the mouth in pulmonic catarrhs, phthisis, etc., and have found that it yields precisely the same results as does the Bergeon's method of treatment. In a few instances the water disagrees with the stomach, but this is unusual; in such cases the rectal injections may be employed.

Water saturated at ordinary temperatures by sulphuretted hydrogen should contain between two and three times its bulk of gas. If allowed to stand, chemical decomposition occurs, with the deposition of sulphur and a marked reduction in the strength of the solution. The solution should therefore always be freshly prepared, not more than two, or at the most three days old. Its odor is of course excessively unpleasant, but its taste is not correspondingly disagreeable, and given in carbonic acid water, few of my patients have objected to it.

At my suggestion, Dr. John Marshall, of the Chemical Laboratory of the University of Pennsylvania, has prepared an apparatus which is so simple that any one, by means of it, can manufacture at an entirely nominal cost, a water which is saturated both with carbonic acid and sulphuretted hydrogen, and which affords an excellent method of administration. Of this water one to two ounces may be given three or four times a day. The cost of the apparatus, boxed for shipment, is only $5.00, so that it is within the means of almost any patient.

This artificial sulphur water will probably be found efficient in all affections in which the natural sulphur waters do good. I have tried it with good results in one case of chronic gout.

Dr. Marshall has also prepared for me an apparatus for impregnating large quantities of water with sulphuretted hydrogen for bathing purposes, so that it is now possible to order for wealthy patients a complete sulphur treatment at home. Perhaps it is just as well to call attention to the fact that the sulphur vapor baths extensively used are not sulphur or sulphurated hydrogen baths, but sulphurous acid baths, and sulphurous acid is no more sulphur than nitrous acid is nitrogen.

A CASE OF PUERPERAL UTERINE RUPTURE.

BY H. V. SWERINGEN, A. M., M. D.,
Of Fort Wayne, Indiana.

I have, in a previous contribution, expressed the opinion that it is the duty of the physician to report his failures as well as his successes. If, however, the number of critical, difficult cases be greater than should fall under the professional care of any single practitioner, the *proviso* that the failures be not in excess of the successes, may, with no little propriety, qualify said duty or its enforcement.

I had thought that I had had about every manner of case that could be found within the covers of the most recent standard treatises on the subject of midwifery, with the exceptions of the Cæsarian section, inversion of the uterus, and extra-uterine fœtation. But a recent case has undeceived me in this respect, and added to my obstetric record an entirely new experience.

Prudence would naturally suggest that a case of puerperal uterine rupture had better remain unreported, especially when the opinions of some of our authorities in regard to these cases are considered, as for instance, the following from the pen of Cazeaux:

"I repeat, therefore, that spontaneous rupture of the uterus is an event of rare occurrence, whilst lacerations produced by the manipulations required in turning, or the introduction of an instrument, are comparatively common. I have met with but a single case of spontaneous rupture; but, unfortunately, have seen quite a number of traumatic lacerations resulting from badly performed operations. The most skillful operator, without any fault of his own, may be the involuntary cause of rupture and cannot be justly censured; yet it is nevertheless true, that almost all such occurrences are the immediate consequence of want of skill or the use of too great force in the introduction of the hand or an instrument. Facts of this nature cannot be repeated too often, for they are calculated to render young physicians, who intend to practice midwifery, more cautious; and to convince them that to have attended two or three women in labor is not all that is needed to render them capable of performing the most difficult operations of our art."

It will be seen by the foregoing quotation that our author is very strongly inclined to the opinion that the great majority of the cases of uterine rupture that have occurred

might have been prevented. However well founded such an opinion may be, it shall not deter me from reporting an additional one—the first to occur in my practice, and in over a thousand cases of labor attended.

The junior members of the profession are entitled to a knowledge of, but rarely have the advantage of profiting by, the unsuccessful practice of their elders, for the reason that the successful experience of the latter only is recorded or in any way revealed, while that which is more or less open to criticism, clouded by unwarranted procedure, or followed by serious or fatal results, is kept hidden not only from the profession at large but in many instances from the patient and friends, and is henceforth known to none save the professional attendants, the fatal results being by them attributed to causes and conditions wholly foreign to the cases.

That the opinions of authors, as of the herein mentioned writer, have not a little to do in preventing many an interesting case from seeing the light of day, or from coming to the surface of the great ocean of clinical experience and being recorded in our various journals, must be obvious to all. But authors are not always right in their opinions, correct in their judgment, or sound in their inferences.

We are too apt to conclude that because we see this or that opinion or statement in *print*, published in "*royal octavo*," bound in the highest style of the art, its title-page bearing the most recent date—the doctrines therein promulgated must be true. No idea could be more erroneous. It is wonderful the respect we pay to type and printers' ink, wholly unmindful of the fact that books partake largely of the imperfections of their creators.

> "'Tis pleasant sure to see one's name in print:
> A book's a book tho' there is nothing in't."

Upon the question now under consideration, when I am reminded of the many exhibitions of wonderful force exerted by the healthy uterus; when I reflect upon the almost incredible degree of power which must be exerted in the performance of traction in certain cases of forceps delivery, and remember that the womb is capable of exerting the same and greater force in its efforts at expulsion in the majority of cases; when I contemplate the almost superhuman power possessed by a perfectly normal womb independent of any volition upon the part of the parturient woman, acting as intelligently and forcibly as if endowed with a mind of its own: I say, when I think of what a healthy womb has done, and is capable of doing in its natural, physiological condition, I not only agree with Professor Cazeaux in saying that "spontaneous rupture of the uterus is an event of rare occurrence," but go further and assert (as my belief) that it *never* occurs in a perfectly normal organ in a labor otherwise normal; that when rupture does occur its cause will invariably be found to depend upon some degenerative changes, some retrograde or other metamorphosis, some alteration of structure, slight or extensive, of the womb itself, and that the usually very tender, mild, timid, often insufficient, fearful-of-doing-some-harm attempts of the young and inexperienced obstetrician to deliver an abnormal case, are but the irresponsible, irremediable, innocent causes—if causes at all—having no more to do with the result than the unaided efforts of nature herself, or other than to excite a manifest predisposition to, or constitute an unavoidable factor in, the production of an immediate rupture.

I have thus prefaced the report of my case in order to encourage the youger members of the profession to hesitate no longer in reporting and commenting upon similar cases, for fear of being censured for want of skill, and also by reason of the fearfully increasing amount of torture to which more especially the American womb is subjected in every conceivable manner for the purpose of preventing conception or of destroying its product. For it is reasonable to predict that these cases will become much more prevalent, and in time form a more important question in the domain of midwifery and gynecology.

At this very moment the writer hereof is cognizant of the fact that a lady (?) moving in the upper strata, if not in the uppermost stratum of society, fully equipped with tents and applicators and other instruments known only to the profession and the initiated, is at work upon herself, having with the same implements upon a previous occasion succeeded in the accomplishment of her object, her physician having yielded to her request for the production of an abortion to the extent only of instructing her how to perform it upon herself. Can it be denied that this practice long-continued will predispose to structural change and seriously compromies the integrity of uterine tissue? This is a question not only for the profession to consider, but it should command the gravest attention of the pulpit and of the bar. It is not at all unwise or improbable to conclude that those parents who resort to all manner of means of preventing and of destroying the product of conception, are more apt to

lose what children they have permitted to come and grow up, and to whom they are so fondly attached, and upon whom they would be glad to lean and depend for support and comfort in their declining years.

The Case.—On Friday night, March 4, 1887, I was called to see Mrs. McNamara, who, it was thought, was in labor, having had slight pains during the whole of the day. The history gleaned from the messenger (the husband), was that her first confinement occurred in Ireland, and was followed by milk-leg, from which she never fully recovered, having ever since had a sore leg, which would alternately break and heal. Her first child lived but a few months. Her second child, now living, a boy 15 years old, seems in good health. Since she came to this country she has given birth to five still-born children in succession and at full term, and has had several miscarriages and false conceptions. Her labors have always been exceedingly slow and tedious, her pains very weak, feeble, and inefficient.

Reaching her bedside in a few minutes, a mere glance at her general physique was sufficient to satisfy me that the prospect for another still-birth was very favorable indeed, unless she was delivered by forceps the moment they could be applied. She was about 43 years old, weighed two hundred pounds, and, as I am informed by a neighbor, drank considerable beer. To the inexperienced accoucheur she would appear to be of the shape and form best calculated to insure a speedy, easy delivery; but I have long since learned to regard the thin, spare, wiry women as the best conservators of my time, trouble, anxiety, and patience in the lying-in chamber. My patient in the present instance was one of those fat women whose muscles are soft, boggy, baggy, relaxed, wanting in tonicity or resiliency, and who require for weeks or months before confinement such remedies as the phosphates, strychnia, etc.

On making a digital examination I discovered a very roomy pelvis, nothing abnormal in its dimensions, the os high up, retracted, indrawn, but undilated, the womb surrounding it in a boggy, soft condition I was ununable to touch any portion of the child. By inspection of the abdominal contour I suspected a transverse presentation, which immediate palpation confirmed, the head being felt on the right above the pelvic brim, and the breech on the left. The woman's pains were aggravating, but accomplished nothing, and could not with a presentation of this character. By external manipulation, I succeeded in getting the head more antero-vertically, but failed to make it engage in the superior strait. I then left her, hoping that nature would correct the position of the child by the time the os should become sufficiently dilated to require my presence.

On the following night, at about the same time, I was again summoned, when I found her in about the same condition as when I left her, except that, notwithstanding her pains were no stronger, the os was dilated and dilatable, being open to the extent of about a dollar or more; but no part of the child could be reached. The line of procedure I had now determined upon was to endeavor, by a external pressure upon the head down toward the superior strait, to apply the long Hodge forceps and deliver by traction, as in an ordinary forceps delivery. But an object so much-to-be-desired was more difficult of accomplishment than it at first appeared to be, and I reluctantly abandoned it for a procedure I feared would be still more difficult, that of version, which, however, was easily and speedily performed so far as the body and arms were concerned, but I had great and unusual difficulty with the head, which I finally delivered with forceps.

Imagine my horror when, upon introducing my hand to extract the placenta, it came in contact with the intestinal surface. A knowledge of what had happened passed through me like an electric shock. It was the most sensitive touch I ever experienced, and was not calculated to be an "antiphlogistic touch," either. There was my hand upon her bowels! Turning the palm upward, I quickly made out the contour of the posterior wall of the womb, feeling not unlike an inflated rubber bag of the size and nearly the shape of an ordinary sized ham, if not larger, no contraction as yet having occurred although there was no hemorrhage.

Withdrawing my hand, I made another and more successful effort to reach the fundus, where I found the placenta as intimately connected with it as Chang was to Eng—the memorable Siamese twins. No cleft, no fissure, no division, not a line of separation or of demarcation could I distinguish by touch: nothing hanging loose but a few shreds of the membranes and the cord. The rupture occurred in the posterior-inferior portion of the womb, through the supra-vaginal segment, but just *when* it occurred I am at a loss to determine, for at no time was there any very special, decided, or pronounced

sign or symptom of shock or collapse, or any great complaint of pain. During the turning, which was very soon and easily accomplished, I let her inhale a little chloroform, but she soon recovered from its effects. I announced to the husband and friends what had happened, gave her a half grain of morphine hypodermically, placed hot bottles around her, and directed the husband to send for his priest, informing him that she was liable to sink in a very short time. She vomited several times in the course of an hour, was quite thirsty, skin cool, and but once or twice complained of a slight burning pain in the abdomen and back. She soon rallied from the shock, asked for beer frequently, talked and joked cheerfully at times, had no chill, temperature remained normal with a tendency to subnormal, pulse weak, feeble, at times hardly perceptible. She remained in about this condition until about the thirty-sixth hour, when her lungs and bronchial tubes began to fill up—she had had bronchitis for several weeks, with a harassing cough—and in the forty-eighth hour after delivery she died in collapse. A post-mortem examination was not granted me; I was *very* desirous of preserving her womb. I immediately addressed letters to Dr. W. P. Whery, of Fort Wayne, and Dr. Frank Greenwell, of Huntertown, Allen county, Ind., who were her former attendants, the former in one and the latter in three accouchements, who have kindly furnished me with data and their opinions concerning her case, and the unfortunate result of her present lying-in; but as this report has already grown far beyond the limits originally allowed it, I shall not, for the present at least, publish their kind letters. Suffice it to quote the following from Dr. W. P. Whery's letter: "Remembering the powerlessness of the uterine muscle on this occasion, I am not surprised to hear of a rupture of the walls. It is probably one of those cases where atrophy is combined with a dilated cavity. The atonic condition of the uterus probably accounts for the frequency of abnormal presentations in this patient's history." Dr. Whery was with her forty-eight hours in the confinement above referred to. The following I quote from Dr. Greenwell's letter: "I attended her again January 14, 1882; the labor was slow; the pains were not strong, but the vertex presented, and as soon as the second stage of labor was reached I gave ergot, and was rewarded for my efforts to encourage delivery by having a dead child to turn over to the family. However, I do not think the ergot had anything to do with the loss of the child. The placenta came away all right, but was in a degenerate condition, showing here and there evidences of an excess of fatty matter. * * * I again attended her May 15, 1883, with the same result as above. The first time I attended her was January 27, 1880, at which time the result was also the same as of the last two deliveries. I think I recall the story of a fall having occurred before the last time I attended her."

ON THE COMBINATION OF IRON WITH SODIUM SALICYLATE IN RHEUMATISM AND RHEUMATIC AFFECTIONS.

BY SOLOMON SOLIS-COHEN, A.M., M. D.,

Chief of Clinic, Out-patient Medical Department, Jefferson Medical College Hospital.

For some four years I have been in the habit, in certain classes of rheumatic affections, usually chronic, of employing a combination of tincture of chloride of iron and sodium salicylate, prepared according to the following formula, which I have been informed by Dr. Rice, of Bellevue Hospital, New York, and other experienced pharmacists, is the first successful combination of these drugs in an eligible preparation. In the House Pharmacopœias of the Philadelphia Polyclinic, where it was first used in 1883, and of Jefferson Medical College Hospital, it is known as the Mistura Ferro-salicylata:

℞.	Sodii salicylatis,	℥iv.
	Glycerini,	f℥ij.
	Ol. gaultheriæ,	♏xx.
	Tr. ferri chloridi,	f℥iv.
	Acidi citrici,	gr. x.
	Liq. ammonii citrat., (B. P.) q. s.,	f℥iv. M.

The mixture is clear, and is not unpalatable. The usual dose is two fluid drachms in water, three or four times a day. The quantities and proportions of the active ingredients may of course be varied according to the intended frequency of dosage, and other circumstances. In cases which are rather subacute than chronic, it is sometimes given every second hour, until the physiological effects of the salicylate are produced, and then at longer intervals. I have also employed it, with apparently good results, in acute articular rheumatism, and in some cases of acute tonsillitis, especially in that group where the diagnosis is at first in doubt between rheumatic angina and diphtheria. Some of my friends have reported to me

good results in acute rheumatism. Its particular applicability is in that group of patients in whom Dr. Russell Reynolds strongly urges the iron treatment—a recommendation endorsed with equal earnestness by Bartholow—namely, anæmic, delicate, poorly-nourished or broken down individuals, usually old people, children, or adolescents, but met with at all ages, whether the disease be acute, subacute, or chronic. In adults, indeed, as a rule, and quite frequently in children, even when the disease is not plainly chronic, the patient will give a history of repeated acute attacks; or there will seem to have been a long series of recurrences, with intermissions of doubtful health. Recognizing the weight of the testimony in favor of tonic, and especially ferric treatment of such cases, and yet desiring to obtain also the specific action of the salicylic compounds, I succeeded, after several ineffectual trials, in obtaining a clear mixture by the use of the formula given above, and four years' experience, latterly, with the ample material furnished by the Out-patient Department of Jefferson Medical College Hospital, has abundantly confirmed my expectations of its usefulness.

219 *S. 17th Street, May*, 1887.

Medical Societies.

ILLINOIS STATE MEDICAL SOCIETY.

FIRST DAY—MORNING SESSION.

The thirty-seventh annual meeting of this society was held in the M. E. Church, Chicago, Illinois, May 17, 18 and 19, and was called to order at 10:30 a. m. by the vice-president, Dr. Elias Wenger, of Gilman, after which the Rev. Charles H. Conklin offered prayer.

Dr. Wenger spoke of the death of the president, D. W. T. Kirk, of Atlanta.

Dr. J. L. White, of Bloomington, called attention to the fact that it was the first time in the history of the Society that it had been called upon to mourn the death of its presiding officer. He then paid an eloquent and fitting tribute to his memory, and said Dr. Kirk was born October 27, 1833. At the age of eighteen he commenced the study of medicine, and graduated in 1854 from the Louisville University. After his graduation, he came to Illinois and located at Farmer City, where he remained one year, and then removed to Atlanta, where he remained over thirty years, and died March 25, 1887.

It was moved and seconded that the society send resolutions of condolence to the family of the deceased, and that the president's chair be draped in mourning as a mark of esteem.

On motion of Dr. Ingals the report of Dr. White was referred to the Committee on Publication, to appear in the necrological transactions.

Dr. A. Reeves Jackson, of Chicago, delivered the address of welcome, and said to his mind the best *prima facie* evidence of the worth, the intelligence, the high professional standing and conscientiousness of the physician, lies in the fact of membership in his or her local State medical society. Many questions pregnant with interest and importance, in the realms of etiology, pathology and treatment, are apparently as unsettled to-day as they were a hundred years ago. This fact, however, should not discourage physicians in the prosecution of their work. He welcomed them in behalf of the entire medical profession of Chicago and vicinity, and extended to them the grasp of the hand. the friendship of the heart, and the hospitalities of the homes of that city.

Dr. E. P. Cook, of Mendota, on behalf of the society, responded in a very appropriate speech.

The Secretary, Dr. W. Graham, of Chicago, read letters of regret from Drs. D. S. Booth, of Sparta, and C. Goodbrake, of Clinton.

Dr. D. B. Brower, of Chicago, then read a paper on

The Practice of Medicine,

calling the attention of the Society first to the new treatment of phthisis, and kindred diseases due to bacteria, by rectal injections of sulphuretted hydrogen, communicated to the Academy of Sciences of Paris, by M. Bérgeon. The literature of the subject for the past year was reviewed extensively. The measure was based upon the physiological fact, established by Claude Bernard, that the introduction of toxic substances per rectum is not so dangerous as their introduction by the mouth, so long as elimination by the lungs is not interfered with. The results of the application of the new method in phthisis are, (1) diminution of cough after a few days; (2) profound modification of the quantity and quality of expectoration; (3) suppression of sweating, and gradual disappearance of moist *râles*, and improvement of the general condition. He then directed attention to the communication of Dr. John H. Skeer, read before the Chicago Pathological Society, on "A Pathognomonic Symptom in

Diagnosis of Tubercular Meningitis," presenting drawings to illustrate the changes which take place in the iris. The symptom to which he alluded is " a small circle which forms in the iris near to and completely surrounding the margin of the pupil. When it begins to appear, it is very distinct, and resembles a wreath of thin white clouds, the edge of which extends to the free border of the iris. In from 12 to 36 hours the whole margin of the iris will be involved, having become of a whitish or yellowish-brown color, and appearing irregular, thickened, and somewhat granular. These changes commence in both eyes simultaneously. This cloud-like appearance is in some cases very evanescent, hence the necessity of examining the iris at each visit. The rings are permanent, and grow narrower and longer with the progressive dilatation of the pupil as the distance advances. After an extensive examination of the literature of the subject no previous record of the symptom could be found, hence the sign might be regarded as a strictly original one by Dr. Skeer. The sign has been observed by several physicians since its discovery, two cases coming under Dr. Brower's personal observation. He next directed attention to the new treatment for tubercular meningitis (which is alleged to be successful), which consists of inunctions of iodoform ointment in large amount. He then drew attention to antipyretics, dwelling somewhat upon the new candidate for public favor, " antifebrin." Antifebrin has an advantage over antipyrin in that it is less expensive, more active, more efficient, and much stronger than the latter. He then considered this drug as a nervine, quoting the literature on the subject and the results of its use in certain cases of epilepsy which it benefited when the bromide of potassium had failed. Favorable reference was made to the application of antipyrin in arresting hemorrhage, and in headache, especially hemicrania, and its results were compared with those of other remedies; the dangerous depresssion following the use of antipyrin was also touched upon, showing that it is an agent which must be used with the greatest caution. The treatment of insomnia by the new hypnotics, urethan and paraldehyde, and especially the former, was next alluded to, Dr. Brower speaking of the reputation that urethan has recently acquired in the treatment of tetanus, several cases being reported as having recovered under its use. In one instance the urethan was combined with chloral. Experience teaches that urethan should be administered in large doses in order to secure the desired effect.

Adjourned.

FIRST DAY—AFTERNOON SESSION.

The society re-assembled, pursuant to adjournment, and was called to order at 2:20 p. m.

Dr. P. H. Oyler, of Mt. Pulaski, read a paper on

Diphtheria,

and expressed his belief that, like scarlet fever, small-pox, and other zymotic affections, it is due to a specific virus; that it is both contagious and infectious, but not in the same sense that scarlet fever and measles are. The exact mode of contagion is unknown. The statement that the disease may be local or constitutional in its origin is not only vague and unsatisfactory, but misleading. Whether the poison is introduced into the circulation by contact with mucous membranes or with the pulmonary capillaries—in either case the origin is local in character. True diphtheria is a zymotic affection, and every theory to the contrary must fall to the ground. The assertion that it attacks only unhealthy mucous membranes is groundless. He had not investigated the nature of the virus chemically, but, from observations and convictions, he bases his treatment upon somewhat different reasoning than that almost universally accepted. No one will deny that cholera is a zymotic disease. He had been taught that in cholera there exists a super-acidity of the blood, and believes that in all other zymotic diseases there exists a super-alkalinity of the blood to a greater or less degree. Assuming, then, that there is an acid condition in the development of the disease, the remedial agent which would meet all the indications and requirements of the case should be sought for and used. Since 1880 he had been using the carbonate of ammonia, jaborandi, benzoate of soda, etc., about the throat, and his results have been satisfactory. He had given the carbonate of ammonia in doses of from 30 to 50 grains. Carbonate of ammonia and benzoate of soda destroy the germ and the medium in which it thrives. Given with milk it stimulates the strength of the patient.

Dr. E. Fletcher Ingals, of Chicago, said he had a few words to say with reference to the first paper presented, and in regard to the new method of treating phthisis. He could not look upon it as a cure by any means. Of the cases in which he had used the gas, the other treatment had been continued as though the new method had not

been employed. He had seen the temperature go down, and within four or five days the sweating cease and the expectoration gradually diminish. However, the temperature in one case had risen again, and things looked badly. One of his patients was unable to take the gas for any length of time on account of the laryngeal symptoms having become worse. It should be distinctly understood that there are dangers to be guarded against in the administration of sulphurous acid gas.

With regard to the paper on diphtheria, the treatment was novel. He had found, however, as he thought the writer himself had, that the treatment in some cases was peculiarly successful from the fact that in going through hundreds of cases in certain epidemics of diphtheria only a few patients were lost; at any rate, such reports were recorded. The old-fashioned treatment of the disease he thought had been more satisfactory. The tincture of iron is a valuable remedy; and gargles and spray are also undoubtedly of great value; but nothing which is liable to exhaust the patient should be used. He thought large doses of carbonate of ammonia would be offensive to a child.

Dr. J. A. Robison, of Chicago, spoke of the sulphurous waters, and said he had given preference to the natural mineral waters, while he understood that Dr. Ingals expresses himself as being better satisfied with the natural water. He would ask Dr. Ingals if he has tested the gas chemically.

Dr. Ingals replied in the negative.

Dr. N. S. Davis said, "I have but a few words to say with regard to the treatment of consumption by Bergeon's method, for I have had no personal experience with it. I do, however, once in a while, get access to the history of cases treated by this method, and will simply relate a case. A young man, well developed, in the suppurative stage of tuberculosis, came to my office: he had been using Bergeon's treatment regularly for ten days, and, according to his report, instead of progressing in the usual way, the expectoration, etc., diminishing, he insisted that his expectoration was increasing, and that he had received no benefit whatever. He only used it for ten days. I encouraged him to continue its use longer; for I consider ten days no fair test. I mention the fact simply to show that in diminishing the night-sweats, and the amount of expectoration, the gas has not been acting in accordance with the results usually obtained. I rise to inquire in discussing remedies for any of the acute febrile diseases whether we are not too apt to keep up an inquiry to find some remedy or some combination of remedies that are to be commenced and given the patient from beginning to end? Most of what I hear is, one man advocates the tincture of iron as the best remedy, another carbonate of ammonia in big or little doses, while still another puts in calomel apparently from beginning to end, and all for the same purpose. Each one has some leading remedy, and something to prop it up on either side. Now, it does seem to me in my experience that these febrile disorders have a definite progress. They present conditions of circulation, general tone, susceptibilities of the system, conditions of secretion—conditions in the exudative products essentially different from each other—as they progress. I have attended a great many cases of diphtheria in former times, and have been through a fair number of epidemics of the disease; some of them were very severe—so severe that I have seen four children in the same family laid on the same table ready for burial. Epidemics differ in their severity, their tendencies, fatality, and their varying amenability to treatment is very evident.

When I have come to a case of diphtheria at the beginning, I find most frequently a dry skin, and a tendency to the checking of secretions. Now, after four or five days have elapsed, the exudation not only on the membranes, but the glands of the neck becomes tumefied, and in a short time it has reached its culminating point. If you watch your patient closely, irrespective of any remedy, paying no attention to medicine, when it has reached that culminating point, you will begin to find a change in the taint of your patient's breath. You will find during the next twenty-four hours after that, if the patient lives, signs of disintegration; you have come to a culmination of the active progressive stage of the disorder, and you begin to notice now what I call the commencement of the stage of suppuration. The membranes and tissues break down, pulse is more rapid, and small ulcers appear in the membrane. There may be in addition offensive muco-purulent discharges from the nostrils and the throat. If remedies are given in the first stage of the disease they are highly beneficial; they tend to promote the natural secretion, diminish the tone of the fever, hold in check the high temperature. You may use calomel at this stage of the disease. I have never had occasion to use iron or carbonate of ammonia; it works well when used at the commencement. Just as soon as the culminating stage is reached the pulse begins to be softer,

weaker, quicker, and, if the case is a severe one, easily compressed. The patient's countenance begins to look a little less florid—it is leaden in color. Next comes the stage of depression, when you may use carbonate of ammonia, tincture of iron, quinine, or anything that will act in the same direction; you will adjust, in other words, your remedies to meet the pathological conditions and indications of your patient in the different stages of the disease. And one of the most important things for physicians to learn is the exact adaptation of their remedies to the pathological relations and conditions of the successive stages of a disease.

Dr. A. K. Steele, of Chicago, said that Bérgeon's treatment was the live question of to-day, and that while it is not applicable to the cure of consumption, and does not destroy the micro-organism, yet it reduces the quantity of sputum and its offensiveness. After the symptoms of sepsis or blood-poisoning have disappeared to a certain extent, it is of advantage as a germicide. He ventured to predict that its life as a therapeutical agent will be as brief as that of the rectal administration of ether in producing anæsthesia for surgical operations.

Dr. E. Ingals said he was reminded of the old proverb, "A new broom sweeps clean," and the longer he lived the more thoroughly he became convinced of it.

Dr. G. L. Corcoran, of Brimfield, thought there might be something in the new treatment, and that it was unwise to criticise it before it had received a fair trial at the hands of the profession. Stranger things had happened, and by further investigation and experimental research something might be arrived at which will affect the tubercle. In his treatment of phthisis pulmonalis he had found nothing so good as iron and arsenic. He agreed with Dr. Davis regarding the disadvantage of using the tincture of iron too early.

Dr. Steele, chairman of the committee on surgery, then read his report, in which he gave a resumé of the

Progress in Surgery

made during the year, referring to the elaborate experimental researches of Dr. N. Senn, of Milwaukee, on "The Surgery of the Pancreas," which supplied data upon which to base rational methods of treatment for such diseases or injuries of the pancreas as may be amenable to surgical interference. The micro-organisms of acute infecting osteo-myelitis have been identified by Rosenbach, Becker, and others. Recently scrofulous, strumous, malignant diseases, white-swelling, and lupus, have been definitely classified as tuberculosis of bones, joints, or synovial surfaces, and rendered curable by recognition af their pathology. It has been demonstrated that foreign substances in the blood-currents are soon covered with a blood plaque (the white thrombus). When stasis occurs from any cause, the third corpuscle or blood-plaque undergoes transformation, adhering to the white corpuscle and the vessel wall, causing a white thrombus. He then referred to the experiments of Dr. Knapp, of New York, who believes that suppuration is caused by bacteria, and has proven that sterilized solutions of chemical irritants introduced into the blood are not followed by suppuration. Fermentation is the decomposition of carbo-hydrates into simpler compounds by the agency of living microbes. Thoraco-plasty was referred to as having been performed with the result of obliterating old pleural suppurating cavities. Surgical operations on the kidneys are becoming more and more frequent. The operations peformed are: Nephrorrhaphy, or suturing a floating kidney; nephrotomy; nephrectomy. Supra-pubic cystotomy is rapidly gaining favor. With regard to antiseptics, he used solutions of bichloride (1 to 500) freely in washing the field of operation. The spray had been abandoned by him during the last three years. Several cases were reported on which he operated himself, one excision of the hip, two leg amputations, one of thigh, three of shoulder. He followed Schede's method in operations upon bone. He used a primary plaster-cast in simple fractures, while in ununited fractures he drilled the unossified band of callus between the fragments in various directions. If this fails he cuts down upon the ends and fastens them firmly with bone pegs.

Dr. B. F. Crummer, of Warren, reported a case of unique

Wound of the Chest,

the lung being extensively lacerated, and profuse hemorrhage having taken place in the right thorax. Of pleuritic effusion he mentioned several cases, and one case of spontaneous recovery from empyema.

It was moved and seconded that the discussion on surgery take place during the afternoon session of the second day.

Dr. Ellen A. Ingersoll, of Canton, chairman of the Committee on Obstetrics, referred to the signs of pregnancy, saying that during the first eight weeks, the changes in the uterus were practically limited to the body of the organ. These changes constitute what is known as Hegar's sign—increase in the an-

terior curvature of the uterus, with increased elasticity of the uterine walls. She then spoke of the management of the secundines, the general drift of professional opinion being toward immediate removal of the uterine contents when the ovum had been expelled. Antiseptics and forceps were next dealt with. In the treatment of puerperal eclampsia the three important factors to be carried out were sedation, or suspension of the reflex functions of the spinal cord, prompt reduction of arterial pressure, and the elimination of effete matter from the system. Veratrum viride stood very high as a sedative. Extra-uterine pregnancy, dystocia, and premature labor, were referred to, the essayist claiming that latroversion at the beginning of labor was a fruitful measure in overcoming and preventing severe dystocia. Porro's operation as modified by Dr. John Bartlett, of Chicago, was alluded to. A supplementary paper on "Does a Retention of the Secundines Necessitate Septic Poisoning," was presented by Dr. W. H. Connibear, one of the Committee on Obstetrics, and read by Dr. Ingersoll, in the absence of the author.

Dr. C. W. Earle, of Chicago, remarked that Hegar's sign was long since observed; no one had considered it worth while to place it on record but Hegar himself, hence it received his name. During the first six or eight weeks, if pregnancy has taken place, we can detect a bottle-shaped condition of the uterus, and a great many practitioners have probably noticed it long before Hegar's sign was promulgated. There is an undue bulging just above the neck. Those who are expert in detecting it say they can detect this sign as early as the 6th or 7th week. Another sign of early pregnancy (not mentioned in the paper) is the discoloration of the vaginal tissues. As regards the removal of the placenta, etc., it demonstrates the fact that pieces of membranes and clots of blood are perfectly inert, if the woman is not poisoned by the practitioner, the nurse, or by something which she does herself. A little piece of placenta, together with a considerable quantity of blood, may revolve in the uterus, and if the finger of the obstetrician or appliances of the nurse do not infect the woman, these foreign masses are inert. Ask any of the operators of Italy, Austria and Germany, after they have gone through an obstetrical operation, will that woman recover? and they will answer, "Yes, she will recover, if I have not infected her." The question is, are we, as American practitioners, prepared to accept this doctrine?

Dr. O. B. Will, of Peoria, entered his emphatic protest against the use of injections, either intra-uterine or vaginal, immediately after labor. He covered all wounds with iodoform, and applied the pad used by Garrigues, of New York. His results were highly satisfactory. He favors the immediate removal of the secundines.

Dr. S. H. Stevenson, of Chicago, said there were two methods of dealing with the secundines—the conservative and the heroic. She adopted the conservative method, if the patient was under perfect antiseptic control, but if not, the physician was justified in using some violence to the uterus. With regard to the physician or nurse poisoning the patient, it leaves no room for autogenetic poisoning. No physician of experience can doubt that frequently the patient has within her the germs of sepsis, which develop at the puerperal period, without being conveyed to her by doctor or nurse.

Dr. E. P. Cook, of Mendota, favored early removal of the placenta.

Dr. Ingals never used injections, unless there was evidence of decomposition, but relied on nature, and maintained that labor was a normal process requiring little interference.

Dr. G. W. Nesbitt, of Sycamore, thought there should be some rule in regard to the treatment of abortions and retention of the secundines. He favored emptying of the contents of the uterus as early as possible.

Dr. J. H. Hollister, of Chicago, said he had practiced medicine thirty-nine years, and his results were usually very good, relying principally upon the conservative method.

Dr. E. Wing, of Chicago, endorsed the statements of Dr. Earle, that there was no such thing as autogenetic infection.

Papers on obstetrics were referred to Committee on Publication.

Society then adjourned to Wednesday at 10 a. m.

(To be continued).

CHICAGO MEDICAL SOCIETY.

Stated meeting, April 18, 1887.

The President, W. T. Belfield, M. D., in the chair.

Discussion on the Treatment of Pulmonary Affections by Gaseous Enemata, with Exhibition of Apparatus.

The President: During the last twenty-five years various specifics for pulmonary tuberculosis have been announced by enthusiastic physicians, and have successively

secured more or less attention from the profession, yet none of these has secured in the hands of others the results claimed by its discoverer. The benzoate of sodium treatment of Rokitansky accomplished nothing in other hands; the phenic acid injections of Déclat were powerless to arrest the disease in any but his own hands; the eucalyptol treatment of Roussel failed in the hands of other investigators. The latest method of treatment—that recommended by Bergeon, of Lyons, after two years careful observation—has, unlike its predecessors, met with almost unanimous approval at the hands of those who have tried it, including physicians in the Paris and Philadelphia hospitals and several practitioners in our own city. Since the method not only promises well, but is also universally accessible to the profession, it has been deemed advisable to present the subject to the members of the Society in a preliminary discussion this evening. There will be presented communications from Bergeon, of Lyons, Bruen, of Philadelphia, as well as the experience of several gentlemen who have used the method in this city.

Dr. Francis J. Crane then read a paper entitled.

Bergeon's Method of Treating Phthisis by Gaseous Enemata.

In January last, the *New York Medical Record* contained an article headed "A New Treatment of Phthisis," which gives a brief outline of Dr. Bergeon's method of administering carbon dioxide mixed with sulphuretted hydrogen gas, and referred to an article published in the *British Medical Journal*, of December 18, 1886. This described in full the apparatus and mode of using it, and stated they had been procuring beneficial results by the method, and that Prof. Cornil, of Paris, had also become an enthusiastic supporter of it. This led me to write to Dr. Bergeon, and in the course of my correspondence, he presented me with an apparatus, as well as with the treatise of Dr. Morel, read before the French Academy last June, and also one by Prof. Cornil. These are so exhaustive that I have embodied in this paper only the essence of both, as follows:

New Treatment of the Diseases of Respiratory Organs and Septicœmia by the means of Gaseous Enemata, according to M. Bergeon's Method. By Dr. V. Morel.—It would seem from the statements of physicians who have tried either to prevent the development or the proliferation of the bacillus, or to destroy it, that it is the one thing which we have to overcome in the treatment of phthisis. In reasoning by analogy with other contagious diseases, as, for instance, cholera and hydrophobia, it might be urged that the bacillus is not the immediate cause of the morbid phenomena of tuberculous affections. It is known that, aside from miliary tubercles, which invade the lungs and are the cause of the patients' symptoms, the gravest phenomena of phthisis are due to the septicæmia, which poisons the patient, and is caused by the suppuration of the tubercles, which, brought in contact with air, undergoes putrefaction and is absorbed into the system. The bacillus works, then, by producing lesions of texture, which become fatal to the organism by rapidly destroying, or, by undergoing softening and absorption, produce septicæmia. To use Darembourg's expression: "The bacillus is nothing, but septicæmia is everything."

In acknowledging that it is not necessary to ascribe to the microbe all of the morbid phenomena of phthisis, it is not less true that its presence is to the organism an incessant and real danger, and that consequently, in endeavoring to discover a remedy for the lesions which it has produced, it is necessary to destroy it, or at least to neutralize its action. For this purpose such agents as sulphuret of hydrogen, bisulphide of carbon, and other antiseptics, mixed with pure carbonic acid, are employed.

Principles of Bergeon's Method.—The first mode of treatment thought of consisted in applying by inhalation some substances having parasiticidal properties. It is known that antiseptic substances are poisonous, when introduced into the arterial system, either directly or by inhalation. Claude Bernard has shown that poisonous gases introduced into the arterial system through the lungs produce toxic effects almost instantaneously. Besides, the antiseptic substances have an irritating action, and this action, operating on diseased lungs, will only increase the existing lesions, while their unpleasant odor arouses a refusal in the patients to their use; this is probably the reason why so little success has been obtained by inhalation in the treatment of phthisis, and is conclusive proof that the introduction of antiseptics by the stomach is preferable; for Claude Bernard has shown that when a poisonous or medicinal substance is introduced into an organ distant from the arterial system—into the digestive tract, for instance—it cannot enter the arterial system, because it is expelled before reaching it. It must pass through the portal system, the hepatic veins, and the pulmonary texture, there to be exhaled, or it can be expelled by the liver with the bile.

It is well established by experiments that the introduction of poisonous substances in the digestive tube may be done without danger by taking certain precautions, of which the most important consist in not injecting too large quantities at once, and not injecting more before the first has been completely eliminated. What avenue ought to be chosen—the stomach or the rectum? In both cases, the medicament will have to pass through the portal vein, the liver, the hepatic vein, the right heart and pulmonary arteries; but we think the rectal way is preferable, for the patient cannot take a dislike to the antiseptic substances on account of their disagreeable odors.

Gaseous Enemata in the Therapeutics of Respiratory Organs, Pulmonary Phthisis, Asthma, Whooping-cough, Bronchitis, Bronchiectasis, Bronchorrhœa, Pulmonary Catarrh. By M. Cornil.—The principle of the action of gaseous injections and of their rapid elimination by the lung, has been given by Claude Bernard. He showed that when sulphuretted hydrogen is injected into the rectum of an animal, the gas is expelled by the lungs; he proved that we can so inject it in almost unlimited quantities, without causing harm; whereas its introduction by inhalation rapidly occasions grave accidents and the animal's death. However, to introduce sulphuretted hydrogen, or any other gas or vapor, into the economy per rectum, for the purpose of destroying the micro-organisms which exist in a number of diseases, it was necessary to find a gaseous vehicle, inoffensive to the economy, and easily tolerated by the bowel.

Carbonic acid gas admirably answers the purpose; it is very easily borne by the colon, rapidly absorbed and afterward expelled by the lung, with the medicinal gas which it holds. This gas itself, in all probability, plays a very important part in this new treatment of pulmonary diseases.

Dr. Bergeon, who inaugurated this method, published a few months ago the first results obtained in the treatment of pulmonary phthisis by this method. Physicians of Lyons, Paris, Geneva and Marseilles who have treated phthisis by the method, have generally obtained a very rapid disappearance of the phenomena of pulmonary suppuration, and progress towards a state of health with all the signs of cure.

Concerning the patients I have treated by this method, I can now assert that the results I predicted three months ago have been achieved. The patients whom I considered cured have no more expectoration, and give on auscultation stethoscopic signs which denote the presence of quiescent cavities, or cicatrized lesions. Some of these patients have been obliged to return to a life of labor; nevertheless their respiratory organs have stood the test, and the amelioration obtained has been permanent.

While many patients whom the expectoration once so exhausted, now have only 3 or 4 grams of sputum a day, at the beginning of the treatment it was from 250 to 300 grams. We have found bacilli, it is true, in the sputa of these patients; yet it remains to be discovered whether these bacilli which continue to exist after the return to health have kept their functional activity or not. Whatever may be the mode of action of carbonic acid introduced by intestinal absorption in the venous blood and afterward expelled by the lung, it can be said from the observation of patients that this gas, filled with proper medicinal substances, greatly modifies the respiratory function, and makes the hematosis more complete and easy. It gives a sensation of well-being, followed by an increase of strength and weight, a diminution of fever and night-sweats.

The following precautions must be observed in giving this treatment. 1. The CO_2 ought to be as pure as possible, so as not to inflame the bowel. That obtained by the reaction of dilute sulphuric acid on the bicarbonate of soda has always been perfectly absorbed by the bowel without producing any toxic effect.

2. The gas should be collected in a receiver from which the air has been expelled.

3. Make the injections just before a meal, or at least three hours after, and never when the patient is weary. It is necessary to be very cautious in experimenting with other medicinal substances, for if, although the sulphuretted hydrogen is inoffensive, other agents, as turpentine, chloral, ammonia, iodine, bromine, ether, etc., may not be, and might be, the cause of an inflammation of the intestinal mucous membrane.

It is not necessary that the dose be large; by injecting twice a day 4 or 5 litres of carbonic acid gas passed through 500 grams of sulphur water, we rapidly notice the disappearance of all the phenomena of pulmonary suppuration, either in its acute or chronic state.

Bergeon's method has been successfully experimented with by Dr. Chantamesse, in his service at St. Antoine Hospital, during the months of August, September and October. The following are his results: "Two patients brought to the hospital suffering with violent attacks of asthma were, half an hour after

the injection with sulpho-carbon vapors, entirely relieved of the dyspnœa. The treatment having been continued for a few days, the breathing was relieved, and the attacks were not repeated during the time they remained." Nine patients giving general and local signs of pulmonary tuberculosis, with tubercular bacilli in the sputa, have obtained very great amelioration from this treatment. The increase of weight has been rapid, one pound, and sometimes as much as 35 oz. a week; cough and expectoration have largely ceased. We always find the bacilli in the sputum, however. These patients have been under treatment for one month and a half. One of them has increased nine pounds in weight.

I have used this treatment in four cases: two of phthisis, one of intussusception of the bowel, and one of spasmodic croup. In the croup and intussusception it operated like a charm, overcoming both almost instantly. In the case of croup I used the bisulphide of carbon, and in half an hour the little patient was sleeping, apparently as well as ever.

Case 1. Mr. W., aged 26. Two sisters and a brother died of phthisis; he had been treated by various physicians and changing climate (having been to Colorado twice) for over three years. The right lung was nearly useless, as it contained a cavity corresponding to nearly if not quite half of its original capacity. Nowhere on this side could vesicular respiration be heard, while the left apex likewise yielded unmistakable signs of disease. There were œdema of the feet, incessant cough, broken sleep, watery stools and ravenous appetite, although he could not retain anything on the stomach; temperature 102° F. After the first injection of bisulphide of carbon, given in the evening, he slept well for three hours, and was bothered very little with cough, but on rising in the morning, to use his own words, he came near strangling for want of a cough, which he finally got, and expectorated a pint in one paroxysm. I then used the sulphuretted hydrogen water and he improved very fast; in one week he had a normal temperature; night-sweats almost entirely stopped; expectoration was much less, and he was able to wear his shoes, which he had not been able to do for over six weeks. Unfortunately, however, at the latter part of the second week he ventured out in one of our rainiest March days, took cold, and his death, two days later, cut short the record of what might have proved almost a miracle.

Case 3. Mrs. W., aged 34, widow, having lost her mother and older sister from phthisis, applied to me for some heart trouble. Complained of a dizzy sensation on rising from a recumbent position; feet swollen; hectic flush; considerable dyspnœa; slight cough with no expectoration. *Diagnosis:* Incipient phthisis with heart complication? She had noticed, also, for about a week, some night-sweats, which did not last, however, after the second administration of gas. She improved so rapidly that she only made seven visits in all, and pronounced herself cured. There is, however, no doubt but she will have a return of symptoms upon the slightest provocation.

This comprises all my experience. But these are facts, and facts are stubborn things to deal with. In regard to the best mineral water, I wish to say that, after trying the Lafayette, Ind., the Blue Lick, Ky., and the Ypsilanti, Mich., mineral waters, I am satisfied that the Ypsilanti mineral water is just what we want. It contains 20 cubic inches of gas to the gallon, and is so strongly impregnated with it that I use it over a second time by having solid rubber corks to replace the perforated ones when I have got through using the apparatus. Mr. St. Clair, President of the Company at 88 Randolph St., has kindly furnished a case of 12 quarts of the water, which I have forwarded to Dr. Bergeon, in hopes that it may compare favorably with the Eaux Bonnes water which he is using. I have also had an apparatus made by E. H. Sargent, which I think takes the place of Dr. Morel's very well, differing from it only in point of cheapness, costing but a little more than one-half the former.

The true place of this mode of treatment cannot be established until the experience of careful observers has been given us, years hence. I wish, therefore, to urge the profession to investigate the matter fairly, since time, I am confident, will prove that Dr. Bergeon has been one of the greatest benefactors of the age.

The President: This method of Bergeon has been extensively used in the Philadelphia Hospital, chiefly by Dr. Bruen, who has kindly furnished a resumé of his experience with it, which the Secretary will read.

"PHILADELPHIA, April 11, 1887.

"The experience thus far obtained in the Philadelphia Hospital in the use of Bergeon's treatment of consumption by rectal injections of carbonic acid gas impregnated with sulphuretted hydrogen, has been highly encouraging.

"In the *Medical News*, of April 2, 1887, a

statement of clinical results thus far secured in my wards was presented. These results indicated that the element of suppuration in pulmonary phthisis was usually very positively influenced. The night sweats have been controlled in twenty-five cases without an exception. The temperature has been modified even in the most advanced cases, and in some instances in which the disease has been extensive it has been brought to a normal point. A peculiarity of the temperature charts seems to be an introduction of a sub-normal temperature in the forenoon. The expectoration has been lessened in all instances, and in some has disappeared. A marked impression has been made for the better on the nervous symptoms which attend the disease, and a more cheerful and sanguine spirit has followed the therapeusis.

"It would seem justifiable to conclude that we have a most important therapeutic agent in the gas enemata treatment. One case of acute broncho-pneumonia treated on this plan has recovered, and will be discharged from the hospital. The history of her case has been already stated in the article in the *Medical News*. Another case of phthisis with pneumo-thorax under treatment for five weeks, is so much improved that the patient insists on her discharge. The râles have disappeared from this patient's chest (the pneumo-thorax was local and confined to the lower zone of the right thorax), the opening into the lung has apparently closed and retraction of the chest wall is going on. This patient had been ill for a year previous to admission to the Philadelphia Hospital; the pneumo-thorax was noted on admission. She has gained over nine pounds of flesh, expectoration has ceased, sweats abolished. The cough, however, continues as a modified symptom, since she is as yet merely a case of phthisis in stage of arrest, the bacilli of tuberculosis being still recognizable in the sputa.

"Two cases of commencing phthisis, with moist râles, dullness on percussion, harsh breathing, deficient expansion over right upper lobe, and tubercle bacilli in sputa, have recently been placed under the treatment. In these cases, the gain in one week has been most material. The râles have disappeared, and the patients express themselves as benefited. The method of treatment is surely worth a careful scientific investigation.

"In our hands a solution of 5 grs. sulphide of sodium and 5 grs. chloride of sodium in 22 ounces of water has proven the most satisfactory substance to produce the sulphuretted hydrogen. A solution more strongly impregnated with sulphuretted hydrogen has not only been more advantageous, but seemed injurious, apparently inducing pallor, loss of appetite, and in some cases irritation of the bowels. The gas should be introduced slowly; not less than half an hour seems requisite for each séance. From three to five quarts can be introduced in most cases, a gain in the tolerance of the necessary distension of the bowel being rapidly acquired. The absorption of the gas from the bowel is very rapid, and in half an hour the distension will entirely subside. It is sometimes introduced more rapidly, but the gain is in proportion to the time consumed in giving the gas. The carbonic acid can be pumped through the solution containing the sulphuretted hydrogen by the aid of a ball with valve attachment. * * * * *

"We have not obtained as yet satisfactory results from the examination of urine, or breath, nor of the effect of the treatment upon the bacillus tuberculosis.

"EDWARD T. BRUEN, M. D.

"1814 *S. Rittenhouse Sq*"

Dr. R. H. Babcock: My experience with this remedy is rather limited, but it seems to me there are several questions which should be considered in speaking on this subject: *First*, is the treatment safe? *Second*, is it applicable in all cases? *Third*, is it a cure? Practically the treatment is safe under the precautions which are laid down; but Dr. Osler in some remarks before the Philadelphia County Medical Society, narrates a case in which the patient almost succumbed after the first treatment, the gas being charged with a mixture of bisulphide of carbon and sulphuret of hydrogen. We can also conceive of cases in which, on account of limited respiratory power, the rapid administration of the gas by producing distension of the large bowel would seriously embarrass the limited respiratory capacity remaining in the patient. It is also conceivable that an undue amount of distension in cases of tubercular ulceration of the bowel might be dangerous, possibly producing rupture and peritonitis; and it seems to me this is a consideration which would render us cautious about administering this treatment in typhoid fever. I have had no experience and seen no reports of cases of this disease treated in this way. In regard to its applicability in all cases, that has been partially answered in considering the previous question. It has been the experience of Geneva physicians, as reported by M. Wiss, and of De La Roche, of Lyons, that there are cases which cannot tolerate the treatment at all. One

patient who had hæmorrhoids suffered from such colic that the treatment had to be abandoned. Wiss also mentions a case in which the treatment had to be abandoned in the course of a month, although superintended by Bergeon himself. I was asked to administer the treatment in a case in which the lungs were so extensively destroyed that it seemed to me unwise to administer it, though perhaps a small amount of gas might have ameliorated the symptoms; but had it been possible to abate or arrest the disease, the patient could certainly not have lived with such a small amount of lung left. Of course this consideration is one which renders the indiscriminate use of the treatment hazardous. There are cases in which the recovery, or arrest of the disease, has been so complete that the patients are practically well, and have been able to return to their avocations. However, if we are to estimate this thing by the disappearance of bacilli from the sputum we must say it is not a cure. No case is reported in which the bacilli have entirely disappeared. As you know, M. Cornil has instituted a number of experiments on animals with reference to this question, a solution of which we are all looking for with much interest. French physicians are experimenting with a great many other substances.

I am now using the treatment upon two cases, one is bronchitic asthma, but the treatments are too few as yet for me to make any report. I would not wish to say whether the relief that has been obtained is due to the treatment or is merely a coincidence. Another case is a lady aged 34, who has been suffering from phthisis for a year and a half, and who last fall received injections of phenic acid twice daily, without any improvement, who had been taking cabinet treatments from me for six weeks, without improvement, in whom the right lung is extensively consolidated, with a large cavity. In this case the relief for the first week was certainly very surprising. The patient gained in strength and experienced a feeling of well being, or as she expressed it a clearer feeling in her head, a feeling of brightness which she had not had for weeks. She certainly coughed less and expectorated less at a time. Her stools had been clay-colored in spite of everything I could do. At the end of a week they were of a natural color. The movement of the bowels was perfectly natural, her tongue also cleaned off in a remarkable manner at the end of five days. The treatments were continued at my office twice a day, and the patient had to come into the city, so the improvement was perhaps not quite as great as if she had taken the treatment at home. The second week she did not do quite as well, which I attributed to the quality of the mineral water. At the end of two weeks she was improved in respect to all the symptoms which have been related this evening. The night-sweats had ceased, her temperature was lower, but not normal—it ranged from 99° to 100⅘°. I took her temperature at 9, 11, 2, and late in the afternoon, and the highest she had with the exception of once was 100⅘°; it was repeatedly 98⅘°. Her tongue did not remain clean, and her appetite did not improve as I desired. She gained strength, but there was a complication, namely tubercular laryngitis. M. Bergeon states decidedly that tubercular laryngitis has been very greatly improved by this treatment. In the case just mentioned the laryngeal symptoms have improved, but whether entirely due to the treatment I am not prepared to say, as she has had various sprays and one topical treatment to the larynx. Her case is somewhat discouraging owing to the extent of the disease, since it is not entirely confined to the right lung. She has complained of no unpleasant symptoms since the first treatment when she complained of a slight burning at the anus and a desire to evacuate the rectum. Once or twice she complained of a little colic. She is now taking the treatments at home and feels very much encouraged, but the outlook to me is not what it should be. I saw her last Thursday, and I felt disappointed to learn that she is beginning to perspire again.

I think all the precautions have been taken in this case thus far, and it proves that the treatment does not give rapid improvement in all cases; and the fact cited by Wiss, that out of four cases treated in Geneva all died within three months, shows that it does not cure in all cases. However, it is a treatment which is so admirable and furnishes such good results in many cases, that I think all physicians are justified in trying it. Another thing which recommends it is that after the patient becomes accustomed to the treatment it can be handed over to a trusty member of the family to administer. Compared with pneumatic differentiation, it offers a much better chance for the improvement of the patient, although there are cases in which pneumatic differentiation will do what this will not. But thus far this method gives better prospects of benefiting a number of cases than any method which has been placed before the profession.

Dr. W. H. Weaver: A case under treatment at the Chicago Polyclinic, which is

making favorable progress, is one in which there is no doubt of the extent of the tuberculosis in the left upper lobe. The expectoration was quite profuse, and contained an abundance of bacilli. She has been failing for two years, but very rapidly for two months. She had fever, night sweats, prostration, wasting, loss of appetite, but had not taken any medicine of any sort. She came to the Polyclinic dispensary, where I treated her ; the first time giving her an injection of only one pint of gas. Her temperature that day was 101½° ; the next day she returned, and I gave her a quart injection, and her temperature was 102.6° ; the next day, the third injection, her temperature was normal, and I gave her another quart. When she returned for the fourth injection her temperature was normal, and she seemed better in every way; said her appetite had returned, the cough was less severe, expectoration diminished greatly, and the night-sweats almost entirely relieved. At the fifth injection she had a slight rise in temperature; she said she had had no more chills and fever for the last three days. I used a solution of about 5 grains of sulphide of potassium with 5 grains of common salt in about 20 ounces of warm water, which gives about the proper amount of sulphuretted hydrogen gas, at least the patients all say that they feel better and have no unpleasant symptoms. I have given it in three other cases ; one has some pelvic trouble, and the physician who is treating her thinks that it might be a counter-indication to the remedy, but she seems to be better in her general condition, has increased in flesh, and coughs less, and prefers to continue the treatment. Another case of incipient tuberculosis, where the upper left apex is affected more particularly, seems to be improved considerably under treatment. He has been having the treatment one week.

Dr. L. L. McArthur: In starting in with this treatment of phthisis I saw the difficulties that were going to arise in the apparatus, and think I can make some suggestions that will prove valuable. The apparatus presented to-night is not portable, and if the patients are to be treated at home they would either require a separate apparatus for each patient or else one must run the risk of breaking the apparatus. In the first place, I thought of a method of collecting the carbonic acid gas, by taking one of those portable laughing-gas cylinders, to be obtained at any dental depot, to a soda-water fountain and having it charged with carbonic acid gas. There can be stored from 1 to 500 gallons of gas, equally chemically pure with that recommended. This apparatus would simply require the turning of a stop-cock in the tube or opening to permit the gas to escape at any rate desired. If found desirable to continue the use of sulphuretted water, instead of mixing the two gases together first, it could be done by using a wash-bottle and a delivery tube. I believe an equally efficient method is to introduce into this cylinder a solution of sulphide of potassium, which furnishes for every ounce of the sulphide of potassium about a gallon of sulphuretted hydrogen. The carbonic acid formed liberates the H_2S from the sulphide introduced. The strength, according to Bergeon's method, is about half of 1 per cent., or a little less. By a little calculation it will be seen that the carbonic acid formed by the combination of the carbon dioxide and water would set free the hydrogen in combination with the sulphur in the definitely desired quantities, so that it would not be necessary to use the sulphuretted water. In that way the gas could be introduced into the measuring bag and then into the rectum. The cylinder would hold a sufficient amount of gas for many treatments, and as it is easily portable, it could be taken to the houses of patients, and not require them to come to the office.

Dr. R. Tilley: I have had no experience whatever in this method of treatment, but I would like to say a word with reference to the apparatus which I think would certainly make the measurement of the gases used more definite. I think, notwithstanding the doctor's explanation of the number of pressures that may be necessary to constitute a quart, that one individual may require so many pressures and another so many less or so many more, and thus the amount would be somewhat indefinite ; whereas if a bottle of the necessary size was filled full of carbonic acid gas, and then another bottle with a tube attached full of water, the latter could be attached with the necessary tubes and elevated just the same as a siphon, and the water introduced into the bottle containing the carbonic acid gas and passed through the sulphuretted hydrogen water with the required rapidity, and thus it would come much more regularly than could be done by means of this spasmodic pressure of the bulb. I would like to call attention to the fact that there are on sale in this city large cylinders containing absolutely pure carbonic acid gas, imported under the auspices of the Prussian government. The gas is condensed to the liquid state at the place where it flows from

the earth at a great depth, from the natural channels. I do not know exactly where it is for sale, but at some manufactory of soda apparatus; and from communication with some of the druggists here I learn that it is only a little dearer than that which they manufacture themselves. It might be argued, however, that if it was simply a little dearer for the druggists it would not be any dearer for those who make it a practice to administer the treatment in their offices, and it would be a convenient way to obtain the gas with the absolute certainty of its being perfectly pure and always on hand.

I would like to say a word about the marked indistinctness that has characterized some few of the reports. It was a positive relief to me when Dr. Babcock gave his more moderate report. The way in which bisulphide of carbon and sulphuretted hydrogen were confused and interchanged was perplexing. Both these agents are exceedingly poisonous, and it is well to bear it in mind. I had some experience with the sulphuretted hydrogen some years ago in the laboratory, and it was my experience that the inhalation of a small quantity was attended almost regularly with a crop of boils. In any case, I think it would be better to have a more definite idea of the quantities of these poisonous agents than can be obtained by the information given us to-night.

Dr. Walter M. Fitch: For generating the gas we use a common Wolf bottle with three corks, one for a stop-cock for the acid, one for the delivery tube, and one for the safety-valve. This last must not be pressed in too tightly; at one time I had the stop-cock blown out and broken by putting in the acid a little too rapidly. To make the gas we use about a heaping tablespoon of bicarbonate of sodium, covering that with cold water about two inches deep. If we use hot water we make a suds that will foam up and run into the bag. We use the bicarbonate of sodium and sulphuric acid diluted one part in four. The reason for using the sulphuric acid in preference to any other is that, being absolutely non-volatile, none of it will pass over into the bag of carbonic acid gas. To make the gas, the generating-bottle is connected with the bag, which is emptied and tightly rolled, in order to remove all the air. The generator should also be emptied of air by turning in some of the acid before it is connected with the gas-bag. The bags usually hold about one-half of what they are marked—a three-gallon bag will hold about six quarts, etc. If we should over-distend it, the corks would be blown out of the generator. For injecting the gas, the stop-cock is turned off and the bag is connected with the bubbling-tube, which extends to the bottom of the bottle of mineral water, so that the gas coming from the bag may pass down into the water, and, rising up through it, be medicated by the sulphur vapor which it contains. It is injected by means of a hand-bulb. In using the bulb it is important to remember that, since it is intended to be used only with water, the action of the valves is not perfect with gas, and it is therefore necessary that the bulb be held vertically, so that the weight of the valves may assist in closing them. In using it in this way we secure a perfect action which draws the gas into the bottom of the bottle and delivers it through the tube. I have now connected it as in use. The bisulphide of carbon has been mentioned several times. In order to use this it is necessary that the gas be washed, for fear that it may contain impurities; for none of the chemicals we get are perfectly pure, and as they are most likely to contain vapors of hydrochloric acid which are easily dissolved in water, the gas is bubbled through pure water to purify it. Between the Wolf bottle and bulb is inserted an ordinary chemical drying tube, a glass tube three-fourths of an inch in diameter, which is drawn down at one end small enough to have the rubber tube slipped over it. Into the other end is fitted a cork with a glass tube through it; in the drying tube is placed a tampon of cotton, and the requisite amount, usually one drachm, of bisulphide of carbon is placed on the cotton. In passing the gas through this cotton it becomes very strongly impregnated with the vapor and is injected in that manner. I think some Philadelphia physician spoke of an instrument for measuring the gas injected. A very simple way of measuring it when using a small apparatus of this kind, is with the bulb. The bulb will deliver at each compression just so much gas; in order to measure how much is delivered we simply take a measured bottle, invert it over the water with the water filling it, then introduce the rectal tube into the bottle and remove the water from it by displacement, the number of compressions being counted. The bulbs vary in size. I remember the capacity of six now in use: two count 15 compressions to the pint; three count 20 compressions to the pint, and one counts 25. Thus, with each apparatus the bulb must be measured, and knowing its capacity, the gas can be prescribed in as definite a way as any medicine measured out of a bottle.

The President: My experience with this method, extending over less than a month, comprises the observation of one case that impressed me strongly; this was a young man suffering from the last stages of quick consumption, who had been in the care of Dr. H. A. Johnson. He was very feeble, much emaciated, had badly swollen feet and albuminous urine. His temperature ranged from 101 to 103 each afternoon, and he had profuse night-sweats. In addition to these usual symptoms he suffered to an extraordinary degree from laryngeal tuberculosis. He had been unable for many weeks to lie down with comfort, and according to his own statement, had not slept fifteen minutes in three months. Cough was constant and expectoration profuse. About a month before Dr. Johnson had given him three or four weeks to live. I used gaseous enemata, employing the artificial solution advised by Dr. Bruen, twice a day. Improvement began on the second day, and by the fourth day was pronounced. The cough was less distressing and the sweats and expectoration had diminished, the patient was able to lie down and sleep for two hours continuously. He was, however, so evidently near dissolution that I deemed it inadvisable to continue a tentative treatment, and stopped it on the fourth day. Two days later he sent an urgent request for the resumption of the treatment, saying that his former symptoms were returning. However, I declined to use the injections further, and six days after their discontinuance the patient died, nearly two weeks after his physician had expected his demise.

It should be remembered that these injections seem to arrest, not the tuberculosis proper, but the sepsis, which is secondary thereto, and that there are numerous other septic conditions in which benefit may fairly be expected, such as surgical sepsis, diphtheria, puerperal fever, etc. The apparatus furnished by the stores is unnecessarily expensive and inconvenient for a visiting practice. I use an improvised apparatus, consisting of a gas bag, double perforated cork, and an ordinary large wide-mouthed bottle—the whole costing $2.50 instead of $10. The entire outfit can be readily improvised at a little cost and carried in a small handbag.

My limited experience gives me the impression that the artificial solution of the sulphide of potassium is preferable to either the Ypsilanti or the Blue Lick water, because the amount of sulphuretted hydrogen in these waters as we obtain them at the drug store, appears to be extremely variable, while in the artificial solution it can be maintained at a given percentage, or increased or diminished as desired, yet care should be taken to make a weak solution about such as is recommended by Dr. Bruen, since a too concentrated solution of the poison may produce very unpleasant symptoms. This method can be employed by every practitioner as well as by the most expert specialist. If it will accomplish nothing more than the relief of the distressing cough, expectoration, fever and sweats of advanced consumption, it will at least do what can be effected by no other therapeutic measure with which I am acquainted; hence it is to be hoped that it will be submitted to a general test by the profession, that we may quickly ascertain exactly its merits and demerits.

Dr. C. M. Fitch: The remedies that have been offered for consumption in the past are about as numerous as the sure cures that have been offered for cancer and hydrophobia, and have commanded about as much attention from the profession. But this method of Bergeon's comes to us under very different auspices; it comes with a letter of introduction that demands from us respectful attention. J. Henry Bennett endorses Bergeon as a man worthy of credit; and if Bergeon's statements be true, they are of the deepest interest to us all. It is in Bergeon's favor also that he not only asks us to believe something, but he gives us a reason for so believing—a plausible explanation of what he wishes us to receive. He assumes that septicæmia, arising either from the absorption of pus, or the morbid product of the bacilli, is the cause of the formidable symptoms of phthisis, and that if we can antagonize this septicæmia, can undo day by day the deadly work of the bacilli, we shall gain time in which the lesions that have arisen from phthisis may be overcome.

The first case in which I had occasion to test this method of Bergeon, was one of extreme anxiety to me. The patient, a young lady 20 years of age, had previously had exceptionally good health, was well nourished, with a muscular development that seemed to defy fatigue. She returned in July last from a visit to Colorado with a cough which was referred to the dryness of the climate and the inhalation of the alkaline dust, which causes a catarrhal irritation. This seemed a plausible explanation, and as the cough was not urgent, it received but little attention until, in November, she took a cold which resulted in chills for three or four successive days, and seemed to prostrate her greatly. I then examined her chest and, to my aston-

ishment, found extensive and marked consolidation at the apex of the left lung; there was also irritation throughout the remainder of the lung and some moist râles. I was much alarmed by what I found, for the location of the consolidation made me fear it might prove something more than simple pneumonia. Several of our best physicians tendered their aid, but the case failed to improve. The patient lost flesh rapidly, her cough became fearfully oppressive, and her temperature never fell to normal, rarely below 100°, and most of the time 101° and rising to 103°. She had daily chills and profuse night-sweats, and the case presented all the features of acute phthisis. At the last examination, made by Dr. Belfield and Dr. Ochsner, both thought they detected bacilli in the sputum, although previous examinations had failed to show them.

Late in January my attention was called to an article in the *Medical Record*, giving a notice of Bennett's paper in the *British Medical Journal*, which contained an account of Bergeon's method. After considerable trouble I obtained a copy of the paper which contained this article, and went to Sargent's to have an apparatus made, and there learned that they had just made one for Dr. Crane, who kindly allowed me to appropriate it, and ordered another for himself. Knowing nothing at that time of what we might expect in such a case from our different mineral waters, and knowing that Dr. Bergeon recommended bisulphide of carbon as the best substitute, we commenced treatment with the bisulphide, and the effect was surprising. The treatment was commenced seven weeks ago to-day; during the week previous, the temperature had at no time fallen to normal; the lowest point was 100°, and once it rose to 105½°, and night-sweats and chills were constant. The first time the injection was tried very cautiously, only a moderate amount of gas being used. The effect was not specially apparent; the second day the temperature still rose to 103°. That night the gas was used much more freely and with results that to us were somewhat alarming. The next morning the temperature fell to 95°, and it did not rise above 100° during the day; the cough was almost suppressed, although it had previously been very distressing. The next day we did not use the gas quite so freely, but the day following the lung was almost entirely occluded; the mucus seemed to become viscid, and the air was almost shut out from the lung. There was so little elimination of the bisulphide through the lung that we soon began to have marked symptoms of bisulphide poisoning, although in many respects she appeared better; the cough was almost gone, and there were no chills. The treatment was discontinued for about ten days, and then resumed with the Ypsilanti mineral water. From that time there has been a satisfactory improvement, and she is better than she has been at any time since her sickness began; her appetite and strength are improved, and she is evidently beginning to gain flesh; her cough is greatly lessened, and the chills have altogether disappeared. Her night sweats have been absent for six weeks, although during the last warm weather she perspired a little for three or four nights there was nothing in the nature of colliquative sweating, and she seems now in a fair way to recover.

The second case in which I tried this remedy seemed about as hopeless as well could be; the patient was confined to her bed, had been suffering from severe hæmorrhage, chills, night-sweats, and great prostration. There was marked dullness at the apex of the right lung, and the physician who was treating her recognized softening. The husband, whose family were patients of mine, after the physician told him that nothing more could be done, came to me. I told him that I did not know that I could do anything more; the only thing I could suggest would be this new treatment which I had been experimenting with, and which might be of some value. He was anxious to have something tried, and the case was undertaken. At the end of four days this patient's chills, which had existed then about a month, ceased entirely, and have not since recurred. On the ninth or tenth day the sweats disappeared; her cough was relieved from the first, no opiate could have controlled it more completely. The expectoration was also lessened, her appetite has improved, and she is gaining in strength. In all respects I think she has gained as much in the time she has been under treatment as I ever saw a patient gain under any treatment in the same time.

Another case was a young man of scrofulous habit, who has a stiff knee from scrofulous disease of the joint. He has been under treatment about three weeks. There was marked consolidation in his case also, at the apex of the right lung, and every indication of phthisis. He has improved materially; his cough is much lessened and he is gaining in strength. The indigestion and flatulence, which had previously troubled him very much, has disappeared under the use of gas;

there has also been great improvement in his appetite.

A fourth case was a young woman of twenty, who came under treatment some two or three weeks ago.

The case was chronic, was not urgent in character; at the same time I thought there was little doubt of its being a true case of phthisis. She gained rapidly from the first, and at the end of ten days her menses, which had been absent since December, returned, and her cough was so nearly cured that she considered herself well, and without consulting her physician discontinued the treatment.

Another case, that of a laboring man, large and muscular, who has been working where there is a great deal of dust, probably from mechanical irritation had contracted trouble with his lungs. He had repeated hæmorrhages, which caused great loss of strength; there was marked though limited dulness at the apex of the right lung, but the chief feature of the case was the marked loss of strength, altogether too great to be accounted for by the lesion in the lung. There seemed to be some torpidity of the liver, and a little pro-iodide of mercury was given. His strength, either from the gas or stirring up the liver, has very greatly improved.

The other cases I have seen have not been under treatment long enough to justify me in making a report. It seems to me from what I have seen that we have a remedy that is worthy further trial. Whether, or not, it will fulfil the promise of its youth we have yet to see. I have no doubt this remedy will relieve spasmodic asthma, and there are other conditions that it would relieve. In puerperal fever I should try it, using the bisulphide of carbon, but using it cautiously. I also think it would be of value in malignant diphtheria and typhoid fever.

LETTER FROM MUNICH.

THE PATHOLOGY AND THERAPY OF WHOOPING COUGH.

BY PROF. A. VOGEL, OF MUNICH, AND PROF. HAGENBACH, OF BASLE.

In a paper read before the Congress of Physicians, held at Wiesbaden, April 14th, 1887, Professor Vogel said that whooping cough is classified by Gerhardt among the infectious diseases; yet the contagion of whooping cough is of a different nature from that of the acute exanthemata. It has not yet been discovered; and the declarations of Hallier and Letzriech could not stand before the judgment seat of the exact bacteriologist. The short bacilli found in the sputum of those afflicted with whooping cough, by Burger, do not influence Flügge. You must inform yourselves in regard to these long or short characteristic micro-organisms. As concerns the symptomatology, the great clinicians of the last century presented a gastro-pathological theory. In the beginning of the present century the neuro-pathological theory had many followers, but this also fell to the ground, as unsuccessful as was the attempt to prove whooping cough to be a simple bronchial catarrh. There now remains no doubt that it comes under the list of infectious diseases. The essayist here recalled the decision of Linne that the cause of whooping cough was the inhalation of a contagium animatum, and related the latest revelations of the laryngoscope in the hands of Herff, of Darmstadt, and likened it to the ideas of Beau, Rehn, Meyer, Hüni, and Rossbach. The first found the whole throat hyperæmic, the others found only the posterior walls to be constantly diseased. The essayist proceeded in relation to the pathological anatomy, saying that in pneumonia following measles and whooping cough great numbers of microbes were seen by Thaon in the pus and lung cells of the expectorate, and indeed in whooping-cough pneumonia he had found diplococci and bacilli in greater numbers than in diphtheritic pneumonia. Marshall describes two cases where whooping cough was complicated with aphasia, stupor, convulsions, and hemiplegia. C. Wagner reports a case of sub-cutaneous hemorrhage in a five year old boy with whooping cough. In some instances it is a cause of deafness. In the case of a nursing child it is a dangerous and pernicious disease to contemplate; in older children the course of whooping cough is favorable throughout. In an epidemic in Würzburg, 52 children under one year were taken ill, and 13, or 25 per cent., died; 248 were attacked between one and five, and 12, or 4.8 per cent., died; between six and fifteen years 87, of whom 1, or 1.1 per cent., succumbed. Prof. Vogel lamented that the mortality tables followed the age so closely, notwithstanding the therapeutics. The remedies recommended for whooping cough are of two great classes—antispasmodics and disinfectants. In treating the spasmodic cough by narcotics one resigns every chance of shortening the process. Opium and all its prepa-

rations should not be given continuously for any length of time; although a small dose of opium or morphia is a great relief to children who have passed sleepless nights. A combination of cannabis indica and belladona is especially recommended by Vettersen, of Hamar. Of 116 children 83 showed a favorable result, of these 30 were completely cured in from 8 to 14 days. Prior and R. Polt recommended the painting of the oral cavity with a solution of cocaine from 10 to 20 per cent.; the application of cocaine is not entirely without danger, however. The antiseptic treatment strives to shorten the attack by destroying the germs of the disease. A residence in gas factories where the products of the distillation of coal act favorably on the mucous membrane of the respiratory apparatus is first to be recommended. This mode of treatment is sometimes inconvenient, some gases can be generated in the sick-room by the use of benzine and carbolic acid. After frequent experience the author did not depend much on this treatment. The inhalations recommended by Fick, of Coblentz, in which 15 to 30 drops of pure carbolic acid are placed in a cotton ball and inhaled, will be endured but a short time by any child. For general disinfection of the sleeping-room of the patient, Sohn burns about 300 grains of ordinary sulphur to each cubic yard of space. Further investigation in this line is to be recommended. Michael, of Hamburg, blows into the nasal cavities through a glass tube 20 centimeters long some powdered resin of benzoin, and besides this uses sulphate of quinine or nitrate of silver in a 10 per cent. mixture with lard. The reports from this treatment in the hands of other physicians are favorable. Concerning psychical treatment nothing new has appeared in recent literature. No followers have been found for the opinion that whooping cough can only be cured by the rod, fortunately for the poor little patients.

Professor Hagenbach gave a large number of statistics on this subject. 240,000 children have the whooping-cough every year in Germany. In Basle, 1,000 per year, with 12 deaths; in Geneva 11 deaths; in London 80; the rest of England, 22. The mortality is on the average four or five per cent. Noblitz reports the mortality from this disease among the children of his policlinic in Breslau, in the years 1875 to 1885, as seven, or nine per cent. In Basle, during the last eleven years the mortality among children under one year has been 26.6 per cent.; from one to two years, 13.8 per cent.; two to five years, 3 per cent.; five to ten years, 1.8 per cent.; ten to fifteen years, 1.6 per cent. These figures show that whooping-cough is a serious disease in the tender years of childhood. With the greatest mortality we have the most complications.

But what, he asked, is whooping cough? Recent investigations indicate that it is an infectious disease. It comes epidemically; seldom sporadically. In large cities it is endemic and contagious. In whooping cough we have a catarrh of a certain part of the mucous membrane of the respiratory tract, which is connected with the immigration of fungi. At those places, through irritation of filaments of the superior laryngeal nerve, the attacks of coughing are brought on by reflex action.

In discussing the question whether or not we have to deal with a local or blood infection, Professor Hagenbach related the different positions held by Letzreich, Colston, Guerneau, De Mussy, Herff, Rossbach, Heyer, Hüni, Lori of Pesth, Rehn, and Baginsky.

The following may be said with positiveness concerning the nature of the contagion, and the liability of the human race to this special poison in general. The disease is most frequent in the first year of life, and is found with rarity in the first months. The susceptibility is great up to the tenth year; after this age it becomes less. It is contagious in the first and second stages. So long as mucus is produced, the disease may be carried. Outside of the human body the contagium seems to be unable to exist for any length of time. The reader then discussed the prophylaxis. Schools for small children should be carefully watched, and children with suspicious coughs kept away as long as they cough in paroxysms. The expectorated material must be carefully removed. If the disease spreads, the school should be closed. The changing of air and place for children affected with whooping cough is often the cause of an epidemic in places free from the disease. Prof. Hagenbach then proceeded to treat of the therapeutics, much of which he found defective.

Dr. Michael, of Hamburg, discussed the subject, and recommended a method used by him, in which he blew powder into the child's throat; and gave statistics of his success. In more than 100 cases so treated he had more or less improved 75; in 25 cases no success at all. In fresh cases his method proved satisfactory, and also in those which had lasted six weeks. The speaker laid more stress upon the qualitative improvement of the cases than the duration of the disease, and circu-

lated through the congress charts giving the course of the disease under the use of different remedies.

Prof. Heubner, of Leipsic, considered the character of the disease to be that of a virulent catarrh, and not a blood infection. He also exhibited charts showing the number of attacks of coughing per day. Like the former speaker, he thought it possible to render these attacks fewer and lighter, and eventually to cause the shortening of the disease and its cure.

Dr. Schliep, of Baden-Baden, recommended the treatment by the pneumatic cabinet, which he had used. The increased pressure of air in this cabinet acted mechanically as a sedative on the mucous membrane, and increased the inhalations of carbonic acid gas. He found 12 to 20 sittings sufficient to cure a child suffering from whooping cough. As a further remedy, he recommended an emulsion of four grammes of turpentine. He also had good success from fumigating the room well with sulphur.

Dr. Sonnenberger, of Worms, advised the use of antipyrin. He had used it in an epidemic in Worms and vicinity with success; it immediately rendered the attacks milder and shortened their duration.

Dr. Cohen, sanitary officer for Hanover, spoke of the favorable results from inhalations of bromide of potassium, also of the musk preparations.

Periscope.

The Prostate Muscle.

Mr. Reginald Harrison, of Liverpool, has an idea of the prostate which certainly is not in accord with the usually accepted one. By the term "prostate muscle," he means the prostate itself, and apparently considers its glandular function as secondary to its work as a sphincter. He believes that, during life, the prostate never presents its post-mortem appearance of a hard body, of about the shape and size of a chestnut, excepting for a few moments when the bladder is completely empty. At other times, he holds that it is spread out like a funnel, supporting the bladder; the degree of expansion of the prostate varying, of course, with the distention of the bladder. Mr. Harrison goes on to say: "Hence the action of the prostate may be said to be just as continuous as that of the heart." Mr. Harrison invokes, in support of his views, the results of rectal examination when the bladder contains a certain amount of urine. If the shape of the prostate were what it is commonly supposed to be, one would find the greatest hardness and prominence in the median line; but Mr. Harrison points out that the centre of the prostatic area is softer and more yielding to the touch than the sides, where there is a marked ridge presenting more or less tonicity.

Sandalwood Oil in Renal Colic.

Dr. Philbert, himself a sufferer from renal colic at frequent intervals, gives in the *Journal de Médecine de Paris* an account of the effects of sandalwood oil in the last two paroxysms with which he suffered. Having read an article by Dr. Gipoulou, in the same journal, recommending the drug in such cases, as soon as he felt the approach of an attack he took four capsules of 5 minims each. He then went into a hot bath. The attacks had hitherto lasted several hours, but in this instance it was over in less than an hour, and the suffering was not nearly so great as usual. An interval of six months elapsed ere he was again reminded of his trouble by the well-known prodromata. A repetition of the former medication resulted in the complete abortion of the paroxysm, a transient pain in the ureter comprising the entire attack.

Common Salt in Migraine.

Dr. Rabow, of Berlin, finds that half a teaspoonful or more of common salt, taken as soon as the premonitory symptoms of an attack of migraine begin to show themselves, will frequently cut it short in about half an hour; similar treatment has also proved of service in epilepsy, as was remarked some years ago by Nothnagel; the explanation being probably in both cases that a violent reflex action is set up.

—In the *Canada Med. and Surg. Journal* of May, 1887, Prof. Osler reports a medical student as answering the question, "How to treat hæmoptysis?" by the reply: "Plug the cavity with cotton saturated with solution of Monsell's Solutions, dry!"

THE
Medical and Surgical Reporter.
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 *reprints will be furnished, in place of payment, if a request is sent with the manuscript.*

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER will be published in each number. The regular edition for this week is 4,500 copies.

The editions of the REPORTER for May 7th and May 14th are exhausted, and orders are on hand for over one hundred copies of each. We will pay ten cents for each of these numbers, or, if any subscriber does not file his REPORTERS, he will place us under obligation by sending these numbers, and we, in return, will increase the duration of his present subscription two weeks. The address printed on the wrapper of the REPORTER gives the date to which each subscription is paid up, and the change in this date will indicate receipt of REPORTERS by us.

LAPAROTOMY FOR EXTRA-UTERINE PREGNANCY.

The operation of removing the product of an extra-uterine fœtation by an incision through the abdominal wall was first performed in 1594, and since that time, now nearly three hundred years, it has been employed a large number of times for the purpose, practically, of removing an intra-abdominal tumor. This operation is now known as a "secondary operation" when it is undertaken solely to remove the product of conception, after the fœtus is dead. What is known as the "primary operation" is the attempt to remove an extra-uterine or ectopic fœtus while it is living and viable, and during the life of the mother.

Dr. Harris, of Philadelphia, who is an indefatigable investigator in regard to such matters, in a paper in the *Medical News*, May 21, 1887, states that the true primary operation of laparotomy for extra-uterine fœtation has been performed only twenty-five times in seventy-four years, the first operation having been done in 1813, in Berlin.

Thus far the mortality by the primary operation has been at least ninety-two per cent., and it will probably prove higher than this when the operations performed in 1883, 1884, and 1885, are all reported.

These results are in marked contrast to those of the secondary operation, which, when performed not earlier than three months after death of the fœtus, has recently been one of comparative safety. The difference between the mortality of primary and secondary laparotomy for extra-uterine pregnancy is almost entirely due to the difference in the risk of hemorrhage, combined with that of septic infection, which is very great in the former and comparatively slight in the latter. The location of the placenta has much to do in determining the final result. This accounts for the fact that sometimes patients recover who have been operated on only a month after the death of the fœtus, while others have died of hemorrhage when the operation has been postponed four months. The immunity under the secondary operation is also partly due to the changes which take place in the placental circulation after its functional activity ceases.

One of the most interesting features of Dr. Harris's paper is his account of the locations of the placenta in extra-uterine pregnancy. In about one case out of six or seven, he says, the placenta will be found implanted upon the abdominal wall. It may be found in Douglas's cul-de-sac, as was the case in two operations performed by Hildebrandt. It may cap over the superior strait of the pelvis, as in the case of a patient who recovered after an operation by Mr. Jessop, of Leeds. It may be located over the iliac fossa; be attached to the uterus and its appendages; be implanted over the lumbar vertebræ, or kidneys; be attached to the small intestine, stomach, or liver; and it has even been found within the uterine cavity. In all of these locations except the last, there can be no contraction of the seat of attachment of the placenta after the fœtus has been removed, and the process of exfoliation must produce more or less hemorhage. To remove a placenta from its attachment to the viscera during the operation must be necessarily fatal, and it has not been attempted in this class of cases, so far as Dr. Harris knows, for forty years.

Dr. Harris concludes his paper by suggesting that, if the risks of primary laparotomy for extra-uterine pregnancy are to be lessened, it will be by adopting the method employed by Dr. August Martin, of Berlin, in 1881, who ligated the vessels of the placenta and removed it with the cyst; and by antiseptic treatment of the placenta, to prevent its decomposition and separation. If the placenta is implanted over the iliac fossa the cord may be tied and cut off close to the placenta, the cyst cavity washed out with corrosive sublimate water, the cyst opening inverted so as to bring the serous surfaces in contact, and the latter united with sutures, and the abdominal wound closed without drainage.

HYSTERICS AND SAINTS.

Charcot has recently been taking instantaneous photographs of some of his hysterical and cataleptic patients during their attacks, and has observed a resemblance between the attitudes they assumed and the expressions of face they exhibited, and those seen in the pictures of the saints, which are so common in the churches and galleries of Europe. The announcement of this discovery has caused some alarm to certain pious Frenchmen, who have denounced it as dangerous to morality. On the other hand, certain critics, who have no great concern for the reputation of the saints, have welcomed Charcot's discovery as though it put an end to the claims of the saints to sanctity, and showed that the saints were as great humbugs as are the subjects of Charcot's experiments.

In this we believe that the pious friends and the unsympathetic critics of the saints and martyrs are getting the relation of things a little confused. There can be no reasonable doubt that Charcot's experiments on hysteria have produced a type of hysterical manifestations in Paris, which occurs there with very great frequency, and occurs elsewhere very rarely—perhaps never. This type has certain varieties, one of which has been well distinguished as that of religious frenzy. The attitudes assumed by patients in such attacks are most palpable imitations of what they have seen, or imagined, in the Roman Catholic churches of France. For this reason it is by no means strange that hysterical patients should present the attitudes of saints or martyrs in the paintings of the old masters. These paintings, or copies of them, bear a most important part in the unconscious education of the French, and especially of the French women, who furnish by far the greater number of Charcot's patients. And it is much more reasonable to assume that Charcot's subjects are wilful or involuntary imitators of the representations of saints and martyrs than to assume that the saints and martyrs were hysterics. No one need take trouble to defend St. Thomas or St. Stephen, or any other saint, from the charge of having an attack of hysterics when "inspired or possessed." For no painter ever saw a saint in this condition, and it would be no reflection upon the saint if it could be proved that the painter's model, posing as a saint or martyr, had worked himself or herself into the very condition which Charcot's subjects get into when they pose before the apostle of hysterics.

We have therefore no sympathy with the fears of those pious souls who have denounced Charcot's experiments as tending to establish heresy in religion, nor with the gratification of those critics who would be glad if they had this tendency. The similarities Charcot has pointed out have no bearing upon religion whatever, although they have a real bearing upon certain scientific questions of great interest and importance; and their bearing upon scientific matters will be better understood and better appreciated if it is not confused by being mixed up with a matter with which they have nothing at all to do.

THE ACTION OF IODOFORM ON THE BACILLUS OF TUBERCULOSIS AND OF ANTHRAX.

In the Sixteenth Congress of German Surgeons, Prof. Bruns discusses the above question, and gives the results of his treatment by iodoform injections (10 % mixture of glycerin and alcohol) of 54 cases of tubercular abscess. Previous to the injection, the pus was extracted by aspiration. Two or three injections were usually required, though often a single one sufficed. Forty out of fifty-four cases were cured, though many of the cavities were large enough to contain over a pint. In view of the extreme difficulty of healing these abscesses, the results were considered highly satisfactory. The beneficial effect was ascribed to the fact of the intimate contact of the iodoform with the tubercular tissue, destroying it, and producing normal granulation. To prove this action of iodoform on the tubercle-bacillus, several abscesses of demonstrated tubercular origin were opened after injection, and preparations of the walls made for histological study: the

results showed a progressive disappearance of the bacilli in the walls, an increase of granulation, a change of granulation into connective tissue, the absorption and disappearance of exudation. The anti-tubercular action of iodoform was thought to be established.

Prof. Sänger followed Prof. Bruns, and described the results of his experiments with iodoform upon the bacilli of anthrax. Their growth was found to be checked by iodoform, and their reproductive power lessened. There seemed to be an anatomical change of the bacillus, of the nature of a protoplasmic degeneration. The inoculation of mice with iodoform anthrax cultures of one to three days' duration resulted in death in one day. With older cultures death was delayed, until, if cultures older than six days were used, the animals escaped altogether. The power of iodoform to affect the bacillus locally was proved by planting the bacillus in a "pocket" both before and after the same had been filled for sometime with iodoform. The result was in harmony with the experiments above mentioned.

THE PROPER FIELD FOR ATHLETICS.

In the June number of *Lippincott's Magazine* there is a very able and interesting paper by Prof. J. William White, M. D., upon the subject of Exercise and Athletics. In this paper Dr. White does not defend the excesses to which college athletic sports sometimes lead, or approve of indiscriminate attempts to secure big muscles. But he does show, by citing examples from ancient as well as from modern times, that the judicious cultivation of a fine physical development may be expected to produce improvement in the type of the individual, and of the race.

We welcome this contribution to the literature of the subject as being timely and pertinent. The day is gone by when dyspepsia should be considered a necessary accompaniment of a high mental development. The coming man should not have a strong mind struggling against the restriction of a puny body; but the true *mens sana in corpore sano;* the health to enjoy life and light and air, and the strength to share in every work or sport proper to his time of life. To this desirable end nothing can contribute more than a rational understanding of the way to make athletic exercise—especially in youth—contribute to the symmetrical development and maintenance of the body.

The paper referred to is a valuable contribution, and we hope shortly to present our readers with an abstract of its contents.

A NEW APPLICATION OF THE THERMO-CAUTERY.

Prof. Genzmer of Halle (before the XVI. Congress of German Surgeons) advocated the use of the cautery in tuberculous lymphatic glands and tumors which are not amenable to treatment by the knife. Under treatment by the cautery they disappeared. In the case of small lymphatic glands it was only necessary to insert the point of a needle-like cautery into the gland, whilst in larger ones a knife-like instrument was passed through the tumor in all directions. He repeatedly found that the glands or tumors became smaller in a few weeks or disappeared entirely. Since making this happy discovery he has treated many of these tumors in this manner, and is entirely satisfied with the results.

He has also treated in the same manner five cases of tuberculosis of the testicle. The patients would not submit to castration. Of the five, two were entirely relieved by complete disappearance of the swelling, and in the three remaining cases the swelling was reduced. Two cases of goitre were likewise treated by this method. The patient was threatened with asphyxia, so that an operation was indicated. The operation with the cautery was performed three times, and consisted in an incision with the cautery knife three centimetres deep, leaving the blade several seconds in the wound. The result was satisfactory.

FLORIDA MEDICAL AND SURGICAL JOURNAL.

The good will of the *Florida Medical and Surgical Journal* has been transferred to the *New Orleans Medical and Surgical Journal*, Dr. T. O. Summers, of Jacksonville, Florida, becoming an active collaborator of the latter periodical. This combination is a move in the right direction. One of the greatest difficulties in the way of successful medical journalism nowadays depends upon the fact that new journals are often started when there is neither need nor proper support for them. It would be much better if the vigor which is often wasted in a vain attempt to start a new medical periodical were used so as to contribute to the success of those which have already won the confidence and support of the profession.

—Dr. Rush S. Huidekoper, head of the veterinary department of the University of Pennsylvania, has recently performed the operation of enucleation of an injured eye upon a dog, and successfully adapted an artificial eye to the socket.

Notes and Comments.

Home Treatment of Mental Disease.

In the course of an interesting paper in the St. Louis *Courier of Medicine* for May, 1887, Dr. Edward C. Mann says:

In puerperal insanity I have seen good results in home treatment, commencing with a full purgative dose of hyd. chlor. mit., followed by salines and then gin, ether and opium, as I have mentioned, at night to produce sleep. In delicate neurasthenic women with uterine complications, a good nurse, perfect rest, one drachm of Warburg's tincture daily before breakfast, the fluid ext. of coca when indicated; quiet nervousness by either the compound bromide mixture, the formula for which is given below, or by the following:

℞. Zinc. valerianat., ℥j.
Ext. belladonnæ, gr. jss.
M. Div. in pill No. 30.
Sig.—One pill every two hours.

This simple treatment, with massage, milk diet and electricity, will save many cases of neurasthenia and hysteria from an insane asylum. I treat many such every year, admitting them as patients into my own family, and witness rapid cures. There is another form of mental excitement which occurs in women at the climacteric period, and which often runs into insanity that consigns them to asylums for years. I have checked this peculiar form of mania, which is characterized by suspicion, sleeplessness and refusal of food, with hot vaginal douches, given by a trained nurse daily, and the following pill, given every hour, or two hours, as the necessities of the case demand:

℞. Pulv. camph., grs. vj.
Ext. hyoscyam., grs. xiv.
Pulv. digitalis, grs. iv.
Mucil. acaciæ, q. s.
M. Ft. pill No. 6.

This pill can be followed by the compound bromide mixture, the formula for which is here given, until the patient is well:

℞. Sodii bromidi,
Ammonii bromidi, āā ℥ss.
Pot. bromidi, ℥j.
Syr. hypophosphitis comp., f. ℥iij.
Syr. tolut., f. ℥j.
Aquæ menth. pip., f. ℥jss.
Liq. pot. arsenit., f. ℥j.
M. Dose, two teaspoonfuls thrice daily in water.

Port wine at dinner, plenty of malt and hypophosphites, together with that admirable nerve tonic, Warburg's tincture, in one-drachm doses before breakfast. Advancing age brings with it, perhaps, depressing cares and irritating environments, or the brain has been overworked and overwearied, so that very few women reach the menopause with a vigorous and well-poised nervous system. One great reason for this, I think, is that very few women will give the necessary time for the recuperative rest to mind and body. Many women who are inheritors of neuropathic tendencies are attacked by mental disease before the menopause is reached, and are cases of psycho-sensory insanity. They are affected in the moral or emotional part of the mind, while the intellect remains apparently unaffected. It is an insanity of feeling. These women show their mental alienation by a change from affectionate wives, good mothers, and careful housekeepers, to a condition in which they lose all interest in husband, children, and house. Their affections are perverted: they are dissatisfied with everything, and will evince hatred of husband and children, and of those nearest and dearest. Yet the very same woman will join in conversation with strangers with the full command of the intellect, so that a casual or even a careful observer would not imagine that such a case was one of true psycho-sensory insanity. There is a morbid perversion of the affective life and a change in character. The conduct is as bad as possible at home, and fairly good, perhaps, when among strangers. These women are prompt and subtle in finding excuses, and so plausible as to deceive the public respecting their unsoundness of mind. I have seen many such cases during the past fifteen years, and the symptoms I have detailed are perfectly characteristic.

Are the Dangers of High Temperature in Acute Diseases Overestimated?

This was the subject for general discussion at the late meeting of the North Carolina Medical Society. Dr. W. P. Beall believes that if we lose sight of the fact that in typhoid fever the high temperature may be due to the excitement of the system caused by disease-germs, and pour into the patient large doses of quinine, we run the risk of paralyzing the heart. He thinks we are tending too far towards the extreme in the use of antipyretics.

Dr. O'Hagan favors antipyretics when the temperature ranges above 103°. Below that point he gives them sparingly, believing that there is little danger from a temperature under this point. He has even seen a case of typhoid recover after the temperature had remained at 108° for several days.

Dr. J. S. D. Cullen believes if the temperature can be kept down, if only for twenty-

four hours, that this respite will result in ultimate good to the patient. He prefers sponging to the cold bath.

Prof. W. C. Dabney states that when the calibre of the blood-vessels in the skin is lessened, more blood is thrown on the internal organs, thereby augmenting the danger of hemorrhage from the bowels, and this he regards as an argument against the external use of cold water. He does not use antipyrin till the temperature reaches 103°, and then his maximum dose does not exceed 15 or 20 grains.

A Step in the Reform of English Spelling.

Professor Skeat, in a recent number of *Notes and Queries*, says:

"Those who know the whole history of our spelling from the eighth century to the present time best understand the harm done by the pernicious system of trying to transplant Latin and Greek symbols into the English language. The symbols *æ* and *œ* are not English, and are best avoided. Indeed, this is done in practice when once a word becomes common. *Æther and œtherial* have been sensibly replaced by *ether* and *etherial*. No one writes *œternal*. *Solœcism* is now *solecism*, and I trust *primeval* and *medieval* will soon prevail over *primœval* and *mediœval*. Pedantic spellings are most objectionable, because they are useless and unphonetic."

We heartily agree with Professor Skeat, and trust that *diarrhœa*, *leucorrhœa*. *dysmenorrhœa*, etc., will soon give place to *diarrhea*, *leucorrhea*, *dysmenorrhea*, etc.

—The above is from the *British Medical Journal*. To be consistent, however, the *Journal* must also use *edema*, *fetus*, *Cesarean*, etc. The characters *æ* and *œ* are not English, and should not be tolerated in anglicized words.—*Columbus Medical Journal.*

Collodion Coating for Pills.

Instead of keratin, as a covering for pills, pharmacist Bernbeck (in the *Vereinsbl. d. pfälz. Aerzte*) recommends a coating of elastic collodion on account of less difficulty to the druggist in its use. Particularly for naphthaline pills the following formula was shown to be very serviceable:

R.	Naphthalini resublimat.,	ʒ iiss.
	Rad. althææ pulv.,	gr. lxxv.
	Mucil. gummi arab.,	q. s.
	Ft. pilul., 100.	

Dry for some days without heat, and coat with elastic collodion.

Sig.—2–3 pills to be taken three times daily.

These pills were proved by physicians to be most excellent for chronic gastric, and intestinal catarrhs, whose existence is shown both by diarrhœa and constipation. The best proof of the serviceableness and proper manufacture of these pills is the fact that they are not rejected by the stomach with eructations of naphthaline gas—a very unpleasant symptom for the patient. The coating of collodion is only dissolved in the lower bowel, the same as with the keratin covering. In order to render the collodion coating permanent, the pill must be absolutely dry, and this condition is shown by the fact that under pressure of the fingers they retain their shape, and crumble rather than flatten. If they contain in their interior the least moisture, the subsequent unavoidable drying and consequent decrease of size will render the adhesion of the collodion only temporary.—*Deutsche Medizinal-Zeitung*, *May* 2, 1887.

Antipyretic Medication.

F. B. Stevenson, M. D., U. S. N., writes as follows to the *New York Medical Journal* of May 14, 1887:

Sir: The very interesting "Notes on the Use of Opium in Fevers," by Medical Director F. M. Gunnell, U. S. Navy ("Report of the Surgeon-General of the Navy," for 1886, page 85), remind me that I have had strikingly good results from the administration of pilocarpine by the mouth in a case of congestive chills with threatened apoplexy. The chills were checked after a second dose of an eighth of a grain, and a return to health followed. Months afterward the patient died of heart disease. Similar effects could doubtless be obtained by the use of other preparations of jaborandi—for example, the fluid extract. Dr. Gunnell states that "too much quinine is used in the treatment of malarial cases." May it not be that fashion, *sans raison*, is answerable for very much in the administration of this so-called specific? There are yet physicians—thoroughly enlightened and active ones, too—who fail to see the rationale of antifebrile dosing with quinine; their faith lies rather in hygiene and natural forces.

Permanent Sublimate Solutions.

Dr. A. C. Bernays presents the following points of practical value in *The Weekly Medical Review:* It has been noticed by many physicians that solutions of bichloride of mercury very often show a deposit at the bottom of the vessel in which they are contained. Chemical examination of these fluids

shows that so far as antiseptic qualities are concerned they are relatively or entirely inert.

When solutions of this kind are used, either by surgeons in the treatment of wounds, or by gynecologists and obstetricians for uterine or vaginal injections, or by the physician in the treatment of diphtheria, etc., the expected antiseptic results are not obtained. The pharmaceutical chemist, Dr. Stütz, of the University of Jena, has, by a series of most careful experiments, given a method of making solutions of bichloride of mercury, which can be kept an indefinite length of time, and are free from the two obections given above. He found that by adding 7½ grains of citric acid to each quart of water used in making solution of bichloride of mercury, there is no reduction of the $HgCl_2$, and also no precipitate when albuminoid solutions are admixed.

It may be added that solutions made with alcohol or glycerine show the precipitate when diluted with ordinary water, which is not the case if citric acid be added in the proportion mentioned above.

Pain as an Antidote to Opium.

The officers of the Inquisition, years ago, discovered that the most exquisite torture that could be inflicted was by the thumb-screw, or pressure upon the terminal branches of the nerves. Acting upon this hint, the *Medical World* suggests that the physician, on ascertaining that he has a case of opium poisoning, should promptly apply a remorseless pressure to every finger on both hands. This can be done without subsequent injury by winding twine around the last phalanx several times and tightly tying. This will give a pain not unlike a felon on each finger. Rouse the patient occasionally to take some water if posssible. Keep the strings on until the patient complains of pain in one of the fingers—find out which one, remove that string, and so on until the last one is off, and yyu have saved a human life. Very few persons need to die from even a very large dose of opium, if seen in time to apply the requisite pain to counteract it.

Therapeutic Equivalents of Salts of Quinine.

According to Boymond, in *Archives de Pharmacie,* the equivalents for 1 part anhydrous quinine are: of the hydrate, 1.16 part; acetate, 1.18 part; basic muriate, 1.22 part; lactate, 1.27 part; basic hydrobromate, 1.30 part; valerianate, 1.31 part; basic sulphate, 1.34 part; neutral sulphovinate, 1.39 part; arseniate, 1.44 part; basic salicylate, 1.45 part; citrate, 1.49; neutral hydrobromate, 1.64 part; neutral sulphate (bisulphate), 1.69 part; hydroferrocyanate, 1.77 part; acid hydriodide, 1.78 part; tannate, 4.42 part; citrate of iron and quinine, variable; brown quinine, variable.

Chlorodyne.

After reviewing the fifteen different published formulæ for this favorite nostrum, the *Western Druggist* commends the formula of Maltbie, given below, as the best substitute for the British preparation:

Morphine hydrochlor. (mur). . .	32	grs.
Alcohol	3	fl. ozs.
Tinct. cannabis ind.	1	" "
Tinct. capsicum	30	minims
Oil peppermint	12	"
Chloroform	1	fl. oz.
Acid hydrocyanic dil.	2	fl. drs.
Glycerin sufficient to make . . .	8	fl. ozs.

Dissolve the morphine in the alcohol, add the tinctures and the other ingredients in the order named.

Peptone Suppositories.

Sauter prepares these suppositories with cacao butter, each containing twenty-five grains of peptone; they are mixed and kept cold to prevent the fat from becoming rancid. In cases where patients cannot be nourished in the normal manner they serve an excellent purpose, fifteen grains of dried peptone equaling two and a half drachms of meat in nutritive value. Children may be given one suppository four times daily; grown persons, two three times daily. The suppository should be lubricated with olive oil, and the rectum be previously cleansed by an enema.

To Paint a "Black Eye."

A writer in the *St. Louis Medical and Surgical Journal* says: for "black eye" there is nothing to compare with the tincture or strong infusion of capsicum annuum, mixed with an equal bulk of mucilage of gum arabic, with the addition of a few drops of glycerine. The mixture should be painted over the bruised surface, a second and third coating being applied as soon as the first dries. If applied immediately after the injury is inflicted, it will almost invariably prevent discoloration of the tissue. The remedy is also of value in rheumatic, sore, or stiff neck.

Microbe of Yellow Fever.

Freire, Gibier, and Rebourgen describe the microscopic appearances and behavior of this bacillus as follows: The microbe is very mobile; it grows rapidly in bouillon when taken from the blood and urine; a dark substance, like black vomit, and having its odor, forms at the bottom of the tubes of culture. Inoculation with the blood of those dying with yellow fever produces an identical disease. Culture liquids undergo spontaneous attenuation in a few days. Inoculations with attenuated cultures have been very successful in the hands of the writers.

A General Tonic.

The following is recommended by Fothergill:

℞.	Quininæ sulph.,	gr. xvj.
	Strychninæ sulph.,	gr. ss.
	Potassii citratis,	ʒ iss.
	Tr. ferri. chloridi,	f. ʒ v.
	Syrup,	f. ʒ j.
	Aquæ, q. s. ad	f. ʒ iv.

M. Sig.—A teaspoonful three or four times a day.

Cod-liver Oil Lozenges.

Mayet (*Le Progrès Médical*, April 2, 1887,) communicates to the Société de Thérapeutique his formula for preparing cod-liver oil pastiles without sugar for the use of diabetic patients:

℞.	Cod-liver oil,	f ʒ ss.
	Bicarb. of soda,	ʒ ivss.
	Phosph. of lime (bibasic),	ʒ viij.
	Essence of anise,	gtt. v.
	Gum tragac., q. s. ad 100 pastiles.	

—*The World's Medical Record*, May, 1887.

To Relieve Pain of Cancer of Stomach.

Germain Sée's formula for the relief of pain after taking food in cancer of the stomach:

℞.	Tr. conii,		
	Tr. hyoscyami,		
	Ol. anisi,	āā	f. ʒ ij.
	Tr. gentianæ,		f. ʒ j.

M. Sig.—Ten to thirty drops after each meal.

A Sedative Hypodermic Injection.

The following formula is given by Cochrane, who states that its use is without the disadvantages of morphia alone:

℞.	Caffein.,	gr. $\frac{1}{6}$.
	Morph. sulphat.,	gr. $\frac{1}{6}$.
	Atropiæ sulphat.,	gr. $\frac{1}{120}$.
	Aquæ camphorat.,	♏ 20.

Formula for Oil of Male Fern.

℞.	Ol. filicis mar.,		
	Tinct. vanillæ,	āā	♏ xlv.
	Syrup. terebinth.,		f. ʒ vj, ♏ xv.
	Gummi arab. pulver.,		gr. xxx.
	Aquæ destillat.,		f. ʒ vi, ♏ xv. M.

This should be taken at one dose, with an equal amount of milk. Castor oil should be given several hours afterward.—*Journal de Médicine*, April 17, 1887.

A Vermifuge Powder.

℞.	Calomel,	2¼ gr.
	Santonine,	1½ gr.
	Sugar of milk,	15 gr. M.

This powder should be given in a little honey in the morning, when the stomach is empty. The dose is for a child four years old.

Unusual Constipation.

Two cases were recently reported at the Louisville Clinical Society—one a young lady, who from girlhood had had a stool but once a month; and a second lady who had an action from the bowels only when she menstruated.

News and Miscellany.

American Climatological Association.

The fourth annual meeting of the American Climatological Association will be held in Baltimore, Tuesday and Wednesday, May 31st and June 1st, 1887, in the hall of the New Physical Laboratory of Johns Hopkins University, Monument St., near Eutaw. The programme is as follows:

TUESDAY, 2 P. M.

Address by the President, Dr. F. Donaldson, Sr., Baltimore.

Subject—Prophylactic Treatment of those who inherit a Predisposition to Phthisis.

The Philosophy of Climatic Treatment of Diseases of the Chest, Dr. James R. Leaming, New York.

An Analysis of 60 Cases of Asthma, with the Result of Treatment, Dr. F. H. Bosworth, New York.

The Influence of Sea Air on Syphilitic Phthisis, Dr. R. G. Curtin, Philadelphia.

Diseased Conditions for which Sea Air is of Doubtful Benefit, Dr. Boardman Reed, Atlantic City.

An Invalids' Day in Colorado Springs, Dr. S. E. Solly, Colorado Springs.

Reception by the President, Dr. Donaldson, from 5 to 8 p. m.

Evening Session, 8 p. m.

The Causes of Cardiac Failure at High Altitudes: from Biological Laboratory of John Hopkins University, Dr. Frank Donaldson, Jr., Baltimore.

Some Hospital Cases of Phthisis: Marked Improvement under General Treatment, with special reference to Alimentation, Dr. Fred. C. Shattuck, Boston.

Discussion of Dr. Shattuck's paper; introducing the subject of *Gaseous Injections* in connection with Diet, Dr. E. T. Bruen, Philadelphia.

The Local Treatment of Diseases of the Respiratory Organs, Dr. B. F. Westbrook, Brooklyn.

The Treatment of the Final Stage of Phthisis, Dr. John H. Musser, Philadelphia.

WEDNESDAY, MORNING SESSION, 10 A. M.

Observations upon the Sanitary Advantages of Tide-Water, Va.; including Virginia Beach as a Winter Health Resort, Dr. A. Y. P. Garnett, Washington.

Evergreen Forests as a Therapeutic Agent in Pulmonary Phthisis, Dr. A. L. Loomis, New York.

Environment in its Relation to the Progress of Bacterial Invasion of Tuberculosis, Dr. E. L. Trudeau, Saranac Lake.

The Climate of the Sub-Peninsula Pinellas, Florida, Dr. W. C. Van Bibber, Baltimore.

The Climate of St. Moritz, Upper Engadine, Switzerland, Dr. Walter Platt, Baltimore.

The Climate of Southern California, Dr. H. S. Orme, Los Angeles.

Reception by Dr. W. C. Van Bibber, 1 to 3 p. m.

Afternoon Session.

Business meeting, 3 p. m.

Public session, 3:30.

Report of Committee on Mineral Springs, Dr. Clarence C. Rice, Chairman, New York.

Classification of American Mineral Waters, Dr. A. C. Peale, U. S. Geological Survey, Washington.

St. Augustine as a Winter Health Resort, Dr. F. F. Smith, St. Augustine.

Pass Christian, Mississippi, as a Health Resort, Dr. Charles Le Roux, Pass Christian.

Visit to the Johns Hopkins Hospital.

J. B. WALKER, M. D., Philadelphia.
Seretary and Treasurer.

A Tailed Family.

Seven years ago Virchow, in answer to an inquiry by a correspondent as to a specimen sent, prophesied that among certain little-studied races, Africans, Tartars, etc., tails would be much more frequently found than among the so-called Caucasian (Aryan and Shemitic) races. His prophecy has recently been fulfilled, since a Russian anthropologist has discovered a tailed family, in which the peculiarity has been constantly transmitted to the females for generations. The tail was bony and covered with hair, and on an average three inches in length. Virchow has found, in such tails as he has been able to examine, no true vertebral elements—merely a central cord representing the chorda dorsalis. Embryologists have found nothing but the chorda and atrophied medullary tube in the caudal appendage found in all human embryos at a certain period of uterine life. In the case of a child born at Oldenburg, the tail was mobile and coiled up like a pig's tail. These Russian cases seem to show that there are marked racial differences in the retention of this caudal appendage. The average tail found in the newly-born human being is but a persistence of an embryonic feature, like bronchial slits, hare-lip, etc. There is a prevalent popular belief in the existence of tailed races. Lord Monboddo, a predecessor of Darwin, believed the midwives surreptitiously pinched off the tails of the new-born, and on one occasion he was found secreted in a lying-in-room to watch the midwife. The higher apes, the gorilla, gibbon, chimpanzee and orang are as tailless as man, and the tailed man is either a reversion to a lower type or a mere monstrosity. —*Chicago Medical Standard, May*, 1887.

Faith Cure.

In Chicago there are said to be twenty-seven distinct schools or factions of "mental healers;" but they, together with all other irregulars, will have to pass a satisfactory examination, if a bill now before the Illinois legislature becomes a law. It provides: "Any person shall be regarded as practicing medicine, within the meaning of this act, who shall treat, operate on or prescribe for the sick or afflicted. It is furthermore provided that a fee of $25 shall be paid for the examination of non-graduates, and that itinerant vendors of anything intended for the treatment of disease, or who in any way profess to heal disease by any drug, nostrum, manipulation or other expedient, shall pay a license of $100 a month to the Board."

The Medical and Chirurgical Faculty of Maryland.

At the recent annual meeting, Dr. I. E. Atkinson was elected President; Dr. C. H. Jones and Dr. J. C. Thomas, Vice-Presidents; Dr. G. L. Taneyhill, Recording Secretary; Dr. R. T. Wilson, Assistant Secretary; Dr. J. T. Smith, Corresponding Secretary; Dr. E. E. Mackenzie, Reporting Secretary; Dr. W. F. A. Kemp, Treasurer; and Dr. G. W. Miltenberger, Dr. J. E. Michael, Dr. P. C. Williams, Dr. J. S. Lynch, and Dr. Randolph Winslow, Members of the Executive Committee.

An Ovation to Professor Gray.

Prof. Asa Gray, who is here on a visit, is being made much of by his fellow scientists. On dropping into the University to attend a lecture, the other evening, he was introduced to the students in terms which must have been most trying to his modesty. The students received him with a chorus of "*Prosits!*" which were renewed when he left the lecture hall.—*Vienna Correspondent N. Y. Herald.*

The Maryland Academy of Sciences.

Among the officers recently elected were Dr. Christopher Johnston, President; Dr. Powhatan Clarke, Vice-President; Dr. John Morris and Dr. R. T. Wilson, Members of the Executive Committee; and Dr. R. T. Wilson, Chairman of the Section in Archæology.

The Medical Society of New Jersey.

The one hundred and twenty-first annual meeting of the Medical Society of New Jersey will be held in the Baldwin House, Beach Haven, N. J., on June 14 and 15, 1887, commencing at 4 o'clock p. m. on Tuesday.

Items.

—Prof. Billroth, of Vienna, is seriously ill.

—Dr. William Goodell will remove on June 1st to No. 1418 Spruce street, Philadelphia.

—The sixth annual International Hygienic and Demographic Congress, under the patronage of the Crown Prince Rudolph, will be held in Vienna from September 26th to October 20th. A hygienic exhibition will also be held in connection with the Congress.

—"What about the Monroe doctrine?" was asked of a village candidate. "Oh, well, now," said he; "when it comes to that, thar's jest as good doctors now as thar ever was. All this talk about Bright's disease and Monroe's doctorin' is nonsense. Dr. Buck, standin' thar, is a good a doctor as any uv them."

—The sixtieth annual Congress of German naturalists and physicians will meet at Wiesbaden during the week from September 17th to 24th next. In connection with it there will be an exhibition of the latest improvements in medical, surgical and scientific instruments, apparatus and technical preparations, free of rent or tax of any kind to the exhibitors.

—The Legislature of Pennsylvania has voted appropriations to the Orthopædic Hospital, the Veterinary Department of the University of Pennsylvania, and the Pennsylvania Museum and School of Industrial Art. These appropriations will furnish aid to the important institutions named, which will increase their usefulness and improve their value to the public.

—A complete account of the Pennsylvania Hospital from its foundation in 1751 to the present time is being prepared for publication, and Mr. Benjamin Hoopes, the steward, solicits contributions to the publication fund and information about any documents that may be of use in preparing the history. It is believed that there are many letters, documents, and objects of interest bearing upon the early history of the hospital which may be brought to light if attention is directed to the subject, and the hospital is so closely identified with the community that all who are able to do so will be glad to contribute to the accuracy and value of the record which it is now proposed to prepare and publish.

—"Technics," in speaking of the substitution of electro-plating for cremation, says: The expense is light, and in operations on a large scale could be much further reduced. This would, of course, depend largely upon the metal used. A millionaire could afford to leave himself in golden statu quo for the admiration of his quarreling family. Silver would doubtless come within the reach of plumbers and real-estate men; brass would be quite the thing for politicians, insurance men and such, while tin would be good enough for editors and other poor but honest folk. It goes without saying in what metal a doctor would be encased.

—The following formula has been recommended for sticking labels to glass: Select three or four pieces of gum tragacanth, about the size of a coffee berry, and place in a two-ounce wide-mouthed bottle; then pour over

it acetic acid so as to barely cover the gum, and place the bottle aside until the next day, by which time the gum will have absorbed the fluid and become very much swollen. Now add water, stir well, and in a day or two a semi-transparent jelly will be the result. A drop or two of 95-per cent. solution of the best carbolic acid should then be added, and it will keep indefinitely.

—A common trouble with us all is that we fail in our business because we think little of it. No man truly succeeds in any calling who has a poor opinion of it. No man has a good opinion of his business who uses it only to make money out of it. No man can have the best conception of his business who does not esteem it for its usefulness. And the higher we go—if "higher" and "lower" are proper terms to use in considering the different honorable and useful walks of life—the more clearly will it appear that he who esteems his business only for the living or money that is in it, must, if judged by any high standard, be a failure.—*Dr. Hapgood.*

OBITUARY NOTICE.

Dr. Vulpian.

Dr. Edme Felix Alfred Vulpian, Dean of the Faculty and member of the Academy of Medicine of Paris, died in that city on May 18. He was born on January 5, 1826. He received his doctor's degree in medicine in 1854. He became attached to the Museum of Natural History at Paris, and there continued the researches on the nervous system begun by the celebrated physiologist Flourens. In 1867 he was called to the Faculty of Medicine, as Professor of Pathological Anatomy. At this time the charge of materialism had been brought against him, and the Academy Council, before which Vulpian had been denounced as an atheist, elected him to the professorship by only one majority. In 1868, his teachings were brought before the Senate, and his views in regard to religion were again bitterly attacked. In 1872, he was transferred to the chair of Comparative and Experimental Pathology, and he became the the Dean of the Faculty of Medicine in 1875. He was elected a member of the Academy of Medicine in 1869, and in 1876 became the successor of M. Andral in the Academy of Sciences, one of the branches of the French Institute. He was the author of a number of medical works, his studies being chiefly in regard to the nervous system. His most recent appearance in public was in connection with Pasteur's so-called method for the cure of hydrophobia, of which he was a warm supporter. It was Vulpian who encouraged Pasteur to make the first experiments upon a human being in July, 1885.

Dr. James A. Donelan.

Suddenly, on the 14th instant, Dr. James A. Donelan, Sr. Dr. Donelan had resided in Mills county, Iowa, for thirty-three years, and held an exceptionally warm place in the esteem of the public. He was born in St. Lawrence county, N. Y., in 1828.

Official List of Changes

OF STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY,

From May 15, 1887, to May 21, 1887.

Major Morse K. Taylor, surgeon, retired from active service, May 14, 1887. S. O. 111, A. G. O., May 14, 1887.

R. H. White, promoted to be surgeon with the rank of major, to take effect from May 14, 1887.

Capt. Jno. D. Hall, assistant surgeon, granted leave of absence for one month, with permission to apply for one month's extension. S. O. 74, Dept. Col., May 11, 1887.

William N. Suter, appointed assistant surgeon U. S. Army, with the rank of 1st lieutenant, to rank as such from May 16, 1887.

In the Medical Corps of the Navy, for the week ending May 21, 1887:

Passed assistant surgeon L. W. Curtis, ordered to the Quinnebaug.

Passed assistant surgeon J. W. Baker, ordered to the Hospital, Chelsea, Mass.

Surgeon A. F. Price, ordered to board duty, Annapolis, Md.

Surgeon C. U. Gravatt, detachment from Michigan revoked.

Passed assistant surgeon G. P. Lumsden, orders to the Michigan revoked.

Surgeon C. A. Siegfried, ordered to the Quinnebaug.

Surgeon R. C. Persons, detached from the Saratoga.

Surgeon W. G. Farwell, ordered to the Saratoga.

Surgeon W. S. Dixon, ordered to special duty, Baltimore, Md.

Surgeon B. F. Rogers, ordered to the Marine Rendezvous, N. Y.

Passed assistant surgeon Howard Wells, ordered to the Jamestown.

Surgeon J. C. Wise, detached from the Jamestown.

Surgeon H. H. Harvey, ordered to the Iroquois.

Surgeon J. R. Waggener, detached from the Iroquois.

Dr. S. Stuart White, of Frederick, Md., commissioned assistant surgeon in the navy, May 19th.

Press of Inquirer Printing Company, Lancaster, Pa.

WHOLE No. 1579.] JUNE 4, 1887. [VOL. LVI., No. 23.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

SOLUTION FERROUS MALATE.

FOUR GRAINS TO FLUID DRACHM

(Amer. Phar. M'f'g Co.)

DOSE.—30 to 60 drops, four times a day.

Exerts the full therapeutic influence of iron, while it does not constipate, nauseate, produce headache, or cause any of the other unpleasant effects resulting from the use of ordinary forms of iron.

Solution Ferrous Malate will combine perfectly with Acid. Sulph. Aromat. and in this form really represents the therapeutic value of the Tinc. Chloride Iron, rid of all its objectionable features.

The late Prof. Gross, who at one time had occasion to use it in his own case, said, "I am highly pleased with it. I obtained all the benefit from it that I can get from Iron."

Ferrous Malate, Gentian and Cinchona.

(Amer. Phar. M'f'g Co.)

DOSE.—Dessert to table spoonful three times a day.

This is said by Physicians to be a happy combination, embodying as it does, a blood tonic, a stomachic and an anti-malarial, as well as a beneficial conjoint influence that neither Iron, Gentian or Cinchona alone is known to possess.

JOHN C. BAKER & CO, Wholesale Agents,

815 Filbert Street, Philadelphia.

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant. Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

THE CARELESS SELECTION OF CONCAVE GLASSES.

BY S. D. RISLEY, M. D.,

Assistant Ophthalmic Surgeon, Hospital University of Pennsylvania.

The history of the following case is briefly related as a protest against the unscientific selection by young persons, with the aid of badly informed tradesmen, of concave glasses for the correction of a real or supposed myopia.

A. B., a bright intelligent lad, æt. 14, was brought to me because of his failing vision and constant headache. The conjunctivæ were injected, the caruncule swollen, and the tarsal borders scaly and thickened. He could use his eyes only a few moments before profuse lachrymation began, with increased headache. The pain was felt most severely in the brow and temples, but shoots of pain radiated to the vertex and occiput. He was wearing, both for reading and distant vision,—2.50 D over each eye, which he had received at the hands of a jeweler, who also sold spectacles. With these $V = \frac{20}{\text{lxxx}}$ and without them $\frac{2}{cc}$. Jr. No. 2 could be read with difficulty at 8″ from the eyes, but blurred if brought nearer or taken further from the face. He was taken to the jewelers by his parents because of trouble with his eyes at school, which they thought might be relieved by glasses. The ophthalmoscope revealed the following conditions: The entire eye-ground was of an intense flannel red, presenting a woolly appearance, the normal stippling being quite lost. The nerves were dark-red from the marked congestion of their surface circulation, and the retinæ were hazy. In the lower part of the eye-ground, and in a crescentic area embracing the outer half of the nerve in both eyes, there was commencing pigment absorption. The details of the eye-ground could be readily studied with —1. D.

He was directed a solution of sulphate of hyoscyamine gr. ij.–f.℥ij., one drop to be used in each eye three times daily. In twenty-four hours $V = \frac{20}{\text{xxx}}$ without glasses. On the fourth day the condition of the eyes had greatly improved, and he received the following formula for *convex* glasses: O. D. + .50ˢ◯ + .50 cy. ax. hor: O. S. + 1. cy. ax. 90°. With these $V = \frac{20}{\text{xx}}$ readily with each eye. His headache disappeared with the first instillation of the hyoscyamine solution, and did not return. Before the influence of the mydriatic had abated, the conjunctival and other symptoms had also disappeared.

The history of this recent case is given thus in detail, not because of any peculiarity in it justifying its publication, but as representative of cases which now and again occur in the practice of all ophthalmic surgeons. Its publication is therefore warranted only in the light of a protest against the careless and unscientific method of allowing any young person to select almost at random a concave glass, simply because he supposes himself to be near-sighted, or because he seems to see better through a concave glass. Many persons, really needing convex glasses to relieve the eye-strain consequent upon low grades of hypermetropia with astigmatism, will, if left to their own judg-

ment, select near-sighted glasses, and thus multiply their eye-strain by the value of the glass selected. The more skillful opticians in our larger cities are to be commended for the increasing caution they have learned to exercise in this regard; but there are still many venders of spectacles who seem to be utterly ignorant of the danger and injury which they entail upon their patrons.

So much has been said and written of late years on the nature of myopia, that it would seem even the laity should understand that a near-sighted eye is almost synonymous with a diseased eye. This is certainly true in all cases in which the degree of the myopia is progressive. In view of this universally recognized truth, it is obvious that the advice of a physician, and not the help of an optician, should first be sought. Where the aid of convex glasses is needed, but little if any harm is liable to follow their use, even though they may not correct accurately the existing defect which makes them a necessity; but in near-sighted eyes with their progressing pathological conditions and the gradual distension of the eye-ball itself, the case is far different, and the optician is no more justified in furnishing glasses to such cases than is the druggist in prescribing for the physical ailments of his customers.

Hospital Notes.

EPISCOPAL HOSPITAL OF PHILADELPHIA.

Results of Treatment of Phthisis by Gaseous Enemata.

F. P. Henry, M. D., physician to the Episcopal Hospital, presents the following interesting and valuable report in the *Polyclinic* of May, 1887:

The treatment of pulmonary phthisis by gaseous enemata was introduced into the Episcopal Hospital by Dr. Henry M. Fisher, of the medical staff. When I took charge of the male medical ward, on April 18th, I found a number of cases in various stages, to whom the gas was administered twice daily. I questioned them closely, and, with the exception of one, who when admitted was almost moribund, they assured me that they had derived benefit from this novel therapeutic method and were decidedly opposed to its being discontinued. An attempt to insinuate, by a modified Socratic method, that possibly they might be mistaken, was not attended with success. So much for the subjective symptoms. Objectively, there has been a gain in weight in all the cases—eight in number—now under treatment, and in one (Case 1) this has been remarkable. No drugs of any kind have been administered to these patients. The men are weighed in their night-shirts on leaving their beds in the morning. The following notes have been kindly prepared by one of the resident physicians, Dr. H. C. Deaver:

Number of patients now on gaseous enemata in male medical ward—8.

Number of deaths of those who have been on the treatment—2.

Case 1. Male, age 33, German, seaman; height, 5 ft. 10½ in. Was admitted September 11th, 1886. Began gaseous enemata March 25th, 1887. Weight at this time was 145 pounds.

Dr. Fisher had previously given this man four intrapulmonary injections at intervals of four or five days.

March	25th,	1887,	weighed	145 pounds.
"	26th,	"	"	146 "
"	27th,	"	"	146½ "
"	29th,	"	"	147 "
"	31st,	"	"	151 "
April	2d,	"	"	151½ "
"	4th,	"	"	152 "
"	24th,	"	"	155 "
May	7th,	"	"	155 "

Case 2. Male, age 49, shoemaker; height, 5 ft. 9½ in. Was admitted March 28th, 1887. Began gaseous enemata March 29th, 1887. Weight at this time was 113 pounds.

April	6th,	1887,	weighed	111 pounds.
"	7th,	"	"	113 "
"	9th,	"	"	113 "
"	12th,	"	"	113½ "
"	14th,	"	"	112 "
"	15th,	"	"	114 "
"	17th,	"	"	113 "
May	7th,	"	"	114½ "

Case 3. Male, age 23; weaver; height 5 feet 6 inches. Was admitted April 14th, 1887. Weight at this time was 109 pounds. Did not show any signs of improvement until April 25th, 1887.

April	14th,	1887,	weighed	109 pounds.
"	25th,	"	"	109 "
"	27th,	"	"	110 "
"	29th,	"	"	110 "
May	1st,	"	"	111 "
"	7th,	"	"	113 "

Never has weighed this much before, and says he feels perfectly well. Discharged today.

Case 4. Male, age 29; laborer; height 5 feet 10 inches. Was admitted April 17th,

1887. Began gaseous enemata April 18th, 1887. Weight at this time was 127 pounds.

April	15th,	1887,	weighed	127 pounds.
"	17th,	"	"	127 "
"	20th,	"	"	128 "
"	25th,	"	"	130 "
May	1st,	"	"	133 "
"	6th,	"	"	145½ "

Discharged May 6th, very much improved.

Case 5. Male, age 28; painter; height 5 feet 10 inches. Was admitted April 19th, 1887. Began gaseous enemata April 20th, 1887. Weight at this time was 115 pounds.

April	20th,	1887,	weighed	115 pounds.
"	26th,	"	"	117 "
"	28th,	"	"	118 "
May	6th,	"	"	120 "

Case 6. Male, age 32; shoemaker; height 5 ft. 7½ in. Was admitted April 20th, 1887. Began gaseous enemata April 21st, 1887. Weight at this time was 99 pounds.

April	20th,	1887,	weighed	99 pounds.
"	22d,	"	"	102 "
"	23d,	"	"	104 "
"	24th,	"	"	106 "
May	7th,	"	"	108½ "

Case 7. Male, age 42; shoemaker; height 5 ft. 5½ in. Was admitted April 25th, 1887. Began gaseous enemata April 26th, 1887. Weight at this time was 112½ pounds.

April	26th,	1887,	weighed	112½ pounds.
"	28th,	"	"	110 "
"	30th,	"	"	111 "
May	3d,	"	"	112 "
"	7th,	"	"	113 "

Case 8. Male, aged 25; bookbinder; height 6 ft. 2 in. Was admitted April 27th, 1887. Began gaseous enemata April 28th, 1887. Weight at this time was 108½ pounds.

April	28th,	1887,	weighed	108½ pounds.
"	30th,	"	"	108½ "
May	2d,	"	"	109 "
"	7th,	"	"	110 "

In addition, there are three or four cases in the female ward, of which I took charge on May 1st. My opinion with reference to this method of treatment must be reserved until these cases have been longer under observation; but the gain in weight, one of the best criterions of improvement, is certainly favorable.

—Professor Hyrtl, the eminent anatomist, who formerly occupied a chair in the Vienna University, has just been successfully operated on for cataract by Professor Fuchs.

MEDICAL DISPENSARY OF THE UNIVERSITY OF PENNSYLVANIA.

Reported by HOWARD FUSSELL, M. D.

Tubercular Meningitis.

Harry F., æt. 8. Father dead of phthisis; brother dead of tubercular meningitis. At the first visit to the dispensary, November 8, 1886, mother stated she brought the boy, not because he seemed so very sick, but because he acted so much like his brother, who died of typhoid fever. (On inquiry, this brother was found to have died of tubercular meningitis.)

History.—Four or five weeks previously had become averse to playing, had a slight diarrhœa, and was chilly; appetite good; no pain of any kind; slept well. Present condition: Temperature 101.5°, pulse 100, abdomen soft, no tenderness, no typhoid spots, no headache, two or three loose stools a day, tongue *clean*, slight dry cough, no enlargement of spleen, no physical signs in chest. He was seen daily; his temperature ranged between 99° and 103.5°. No other symptoms. The child did not seem sick, and wanted to play, though he was kept quiet from the first.

On November 16, 1886, he vomited for the first time.

November 18. Vomited twice, passages loose, two or three in 24 hours. No spots, belly prominent, slight tenderness in right iliac fossa, tongue clean, pulse 100, temperature 102.4°

November 19. Vomited, headache for first time, bowels loose. No physical signs in chest. Abdomen somewhat retracted; an enlarged mesenteric gland felt to right of spine.

November 20. Much vomiting, headache, noises in head, no pupillary signs.

November 21. Pulse irregular; no pupillary signs.

November 23. Strabismus; irregular pupils; double vision; *tache cérébrale.*

November 26. Convulsive movement of jaw; comatose; purulent conjunctivitis.

November 27. Respirations irregular.

November 29. Wasted away until skin seems tightly drawn over face; belly much retracted; several enlarged mesenteric glands felt; comatose.

November 30. Death.

From the time of the first visit until November 21 this case might, with much reason, have been regarded as one of typhoid fever. The continued fever with diarrhœa,

and no signs pointing to any other affection, would have justified the diagnosis. Fortunately the mother was told in the beginning that it might be meningitis, and not typhoid. This conclusion was reached solely on the history of a death from phthisis and one from tubercular meningitis in the family, and not because the symptoms pointed specially to meningitis. After November 23, of course there was no mistaking the nature of the disease.

Treatment.—From the beginning the patient received 5 gr. of potass. iod. t. d., with such other treatment as the symptoms demanded. Though it was necessarily futile, the boy had the advantage of the treatment which Dr. Louis Smith considers curative in a certain number of cases.

Medical Societies.

ILLINOIS STATE MEDICAL SOCIETY.

SECOND DAY—MORNING SESSION.

The following voluntary papers were read: "Ocular Disturbances from Nasal Disease," Dr. H. Gradle, of Chicago; "The Use of Acetate of Lead in Certain Conditions of the Eye," Dr. F. C. Holtz, of Chicago; "One Factor in the Etiology and One Means of Cure in Puerperal Fever," Dr. C. W. Earle, Chicago; "Jequirity," Dr. E. L. Holmes, of Chicago.

Dr. O. B. Will, chairman of the committee of the section of gynecology, read a report of the progress made in this branch during the past year. It was largely in the way of reconstruction and revision. He alluded to the diverse views respecting the use of certain instruments. One of the few subjects which have attracted attention is pelvic inflammation. Generally speaking, by pelvic inflammation is meant pelvic peritonitis and cellulitis; at least, that accords with the current literature on the subject. The etiology of the affection is not settled. Aspiration is now generally a useful aid in diagnosis. Laparotomy has been recommended as about the only cure for pelvic abscess. Dr. W. H. Byford says it should be done only when the abscess is supra-pubic or intra-parietal. Dr. Fenger says: "When a communication exists between the abscess and the intestinal tract, evacuation of the pus into the bowel is sometimes followed by spontaneous recovery." The speaker in one case made an opening 2½ inches above the anus, through which a catheter was introduced and drainage effected. After dilatation of the sphincter ani no special difficulty was experienced. Injections of carbolic acid were used daily. The patient recovered. To cure pelvic abscess, drainage is not always necessary; aspiration will suffice in some cases. When drainage of the abscess is aimed at, the peritoneal cavity should not be opened. In suitable cases, open up the inguinal canal, insert a glass or rubber drainage-tube, and the cavity may be drained without fear of peritonitis.

Attention was directed to tamponing, as recommended by Engelmann, of St. Louis, and Etheridge, of Chicago.

Dr. Catharine Miller, of Lincoln, read a paper on

Cases of Posterior Displacement of the Uterus in Virgins.

Most of these displacements are caused by accidents of childhood, producing discomfort of the uterus at puberty. Children in whom such accidents are observed are, almost without exception, given to jumping rope. Mothers whose children jump rope freely report complaints of pelvic pain from their little girls. The reporter cited three cases which came under her observation during the past winter.

DISCUSSION.

Dr. J. G. Kiernan, of Chicago, in opening the discussion, said: Much might be said about the effects of certain habits, such as climbing stairs and rope-jumping, upon the uterus. Besides this, however, a woman coming from a defective family is very likely to have uterine displacements. There has recently been considerable reaction against the excessive use of local vaginal applications in the treatment of conditions like dysmenorrhœa, which are undoubtedly the result partly of constitutional disorders. That dysmenorrhœa is a neurotic disorder, there can be no reasonable doubt. In the hospitals for the insane one finds many female patients suffering from local affections, which are the result of constitutional conditions, and proper treatment of the constitutional condition relieves the pelvic disorder.

Dr. G. W. Jones, of Danville: Regarding the points raised by Dr. Will, as to the danger of pelvic abscess opening into the rectum, I wish to record the fact of three such cases in my practice which entirely recovered. With reference to tampons, I prefer dry wool. I have found it the most efficient means for support of the pelvic organs, especially in cases in which there is relaxa-

tion of the soft parts. With regard to retroversion in virgins, my experience has led me to believe that there are many virgins who have been born with retroverted wombs, and that these give them no annoyance. I know of a family, a mother and five daughters, who all have retroversion; in other respects they are perfectly healthy.

Dr. G. W. Nesbitt, of Sycamore: I would like to say, in regard to the use of the tampon, that it is the custom to use absorbent cotton in making it. Absorbent cotton is very objectionable, because when wet it becomes hard and as solid as clay.

Dr. L. G. Thompson, of Lacon: I have been very much interested in the papers presented, and more especially in the practical character of the second one. Regarding Dr. Will's paper, I would say, country doctors do not come across cases of cellulitis and pelvic abscess very frequently. I wish to emphasize one thought in the second paper concerning the importance of considering the liability to uterine trouble in virgins. Many physicians think virgins are not liable to that form of derangement; but my observation has led me to believe that it is much more common than many are disposed to think. Every now and then I find a case of uterine displacement, accompanied by chronic inflammation, in a virgin. In regard to using absorbent cotton I would say that, when it is removed the next day after its introduction, it is as good as anything else; but if I were going to leave it longer than that I should want something different—in other words, a tampon should not be left in longer than 24 hours. I have been in the habit of employing some form of pessary where the uterus must have continued support. Many physicians are opposed to pessaries, but my experience has taught me otherwise.

Dr. J. S. Whitmire, of Metamora: Retroversion of the uterus in virgins is something new to me. It is true nature has some wonderful freaks, and there can be no doubt that certain kinds of exercise in young girls produce displacements and inflammations of the utuers. The profession is disposed to attribute all ills in females to some uterine derangement.

Dr. D. T. Nelson, of Chicago: If the doctor investigates the history of these cases of supposed congenital malposition of the uterus, he will find that something in the dress of both mother and children has caused the malposition. Tight clothes hinder the development of the organ in both mother and children. If this could be rectified there would be an opportunity for improvement.

Dr. Miller heartily agreed with the ideas brought forward by the different speakers, and said tight clothing was an active element in producing displacements of the womb.

Dr. Will: The remark of Dr. Thompson that country practitioners do not often meet cases of pelvic inflammation is a little out of place; for every general practitioner sees more or less of these cases. Many cases of pelvic inflammation, diseases of the ovaries and tubes, originate through carelessness on the part of the physician. Only a few days ago I found, in a consultation room, a sound and speculum lying on a window sill and covered with the dried secretions of the last patient.

Dr. Thompson: I referred to the country physician, not to the practitioner in densely populated centers. I do not think the country doctor frequently meets with cases of cellulitis or abscess of the pelvic organs; at least, it has not been my experience.

On motion the Society adjourned till 2 p. m.

AFTERNOON SESSION.

Dr. D. A. K. Steele gave an epitome of his paper read the day previous, and exhibited some patients on whom he had operated. One was a case of amputation of the shoulder, in which all the joint tissue had been removed.

Dr. P. H. Oyler, of Mt. Pulaski: I have had quite a number of compound, and of compound comminuted fractures. In one case a man was run over by a pulverizer, and two and a half inches of the upper half of the tibia was removed, and the entire integument was cut through, leaving only a portion of the gastrocnemius and the anterior blood vessels. Two physicians had been called, and had decided upon amputation. In the meantime I was sent for, and finding there were enough blood vessels intact, I concluded the limb could be saved by putting it in a thick dressing. The patient recovered. I would like to know why a compound fracture, or a compound comminuted fracture, cannot be hermetically sealed.

Dr. Charles T. Parkes, of Chicago: I have been much interested in the papers presented by Drs. Steele and Crummer. With reference to cocaine, I have used it in some cases with very happy results. Its usefulness is not fully appreciated by the profession, nor is it as often used as it might be. I used it in one case of ununited fracture, where I cut down upon the bone, and no pain was felt by the patient, except when the bone was being divided by the saw. I do not use the wire

in ununited fractures. I have cut down upon one or two cases in which wiring had been practiced, and a fistulous opening had remained—the cause of the opening seeming to be the wire. I have no doubt but that there are times when this method, as well as the bone-pegs, may be used, but a great many cases of compound comminuted fracture recover without any such treatment. I am unable to understand why Dr. Steele uses iodoform to cover the wound surface. It has been shown recently that any form of microbe can be propagated in iodoform. I agree with portions of the paper concerning examinations of the kidney, and also with regard to the necessity of making a median incision for exploration of the bladder.

Dr. Ingals remarked that the suggestion of Dr. Steele relative to the stretching and falling kidney recalled the case of a young married lady who had never been pregnant, and who consulted him for falling kidney. It came well down into the abdomen; it could be returned to its place, but not successfully fixed. The lady became pregnant in the course of time, and gave birth to a live child at full term. She has had several children since. The kidney became firmly fixed during the first pregnancy, and has remained so ever since.

Dr. B. F. Crummer, of Warren, said the point relative to the open treatment of wounds had not been touched upon. Is it not true that in some cases the open treatment is the best, as in crushing injuries of the fingers? Undoubtedly better results can be obtained from such treatment than by closing the wound. He thought the rule should be strenuously adopted to make the incision directly at a right angle to the long diameter of the limb—a point upon which Dr. Steele did not sufficiently dwell.

Dr. Steele closed the discussion, and said: I agree with Dr. Parkes, that wiring and pegging of the bone is unnecessary in many cases. I am in the habit of sprinkling a light film of iodoform over the wound surface in amputations; it is an excellent hæmostatic, especially when dissolved in ether.

The report was referred to the Committee on Publication.

The report of the treasurer showed at the beginning of the present session $1,322.77 in the treasury after the satisfactory adjustment of all claims against the Society.

Dr. Walter Hay, of Chicago, moved that the Illinois State Medical Society subscribe $500 towards paying the expenses of the International Medical Congress.

The motion was seconded by Dr. J. L. Gray, after which Dr. N. S. Davis explained the purposes for which this money was needed.

Dr. Moses Gunn offered an amendment that $750 be subscribed, which was unanimously adopted.

The report of the Committee on Drugs and Medicine was read by Dr. Maria J. Mergler, for Dr. J. G. Tapper. The report dealt with the prevailing evils existing between physician and druggist. It condemned the practice of re-filling physicians' prescriptions, and the practice of pharmacists in selling compounds in the shape of renovators, blood purifiers, etc., and denied that the prescriptions of a physician are in any way the property of the druggist.

Dr. Mergler then read a paper on

The Progress of Therapeutics in Gynecology,

directing attention to cocaine in the treatment of gynecological cases, recommending hydrastis canadensis for cases in which ergot is usually administered; also iodoform and iodoform gauze dressings and antiseptic douching of the uterus and vagina in operations.

Dr. J. H. Hollister, of Chicago, said: The suggestions in the first paper are of the utmost importance, requiring careful consideration in order to decide what our duties are. We stand in a relation to the pharmaceutical profession which ought not to be in anywise antagonistic. There should be some code of ethics to govern the relations between physicians and druggists. A paper should be prepared setting forth the relations of the medical profession to manufacturing druggists and dispensing chemists so fairly as to be received by both as a just exposition of the relations existing between them and us. The abuses are not overstated in the paper.

Dr. Barnes, of Bloomington: This has become a very serious question with me. As far as manufacturing chemists are concerned, I keep a waste-basket in my office to which most of the samples are consigned. It has become the practice in my town for druggists to duplicate a prescription once or even a hundred times. They have a book for the special purpose of recording prescriptions. They not only re-fill for the patient, but for his family or friends.

Dr. N. S. Davis: A physician should never prescribe any manufacturers' medicines, or any compounds put up by anybody else. Every physician should prescribe, if he does not use more than one drug, and he should clearly state the strength of the materials used, designating the Pharmacopœia

of the United States. The dispensing of medicines should be entirely separated from anything else which goes to make up a drug store. In Europe the dispensers of medicines are usually found in small rooms, at a rent of probably $5 per month. In this country, if a person's sickness does not last longer than three days, his drug bill will exceed the charge made by the doctor. The system is entirely false; there is no reason whatever why the sick should pay for marble floors, highly decorated rooms, and all the clap-trap that goes to make up the ordinary drug store. The druggist is all right, but his system is false from beginning to end.

Dr. Samuel Jones, of Chicago, read a paper on

Improvement in the Management of Diseases of the Eye.

In the operation for soft cataract the needle operation is still the one usually practiced. After partial disintegration and softening of the lens, suction is sometimes practiced, to hasten removal of the lens substance. In hard cataract, extraction of the lens is usually effected by Von Graefe's modified linear extraction, as suggested by him, or as modified by others. Manipulation, to hasten the ripening of the cataract in order to admit of earlier extraction, has not thus far been attended by encouraging results, and its practice is not free from danger. Incision of the periphery of the capsule of the lens, as suggested for the escape of the lens, and to prevent continuance of the nutrition of the capsule, thus to avoid the occurrence of secondary cataract, has not met with general favor. Evisceration of the globe is a recent substitute for enucleation of the eye-ball, in cases in which it is desired to avoid danger of sympathetic disturbance of the unaffected eye, and yet to retain enough of the sclerotic coat of the eye, with its muscular attachments, to afford a movable support for an artificial eye. It seems to possess merit enough to warrant a longer trial.

Dr. A. E. Prince, of Jacksonville, in his Report on Otology, called attention to an instrument for regulating the pressure used in inflation of the middle ear. He said, it is impossible to arrive at an estimate of the damage done by the unregulated force employed in the indiscriminate use of the Politzer bag in the treatment of middle ear diseases. To facilitate the method of inflation and diminish its dangers, attention was called to a graduated mercurial column upon which the patient is required to blow. The instrument is essentially a re-curved tube filled with mercury and supplied with a rubber tube, against which the patient is required to blow while the ears are inflated. While the mercury is displaced the air is driven by the bag through the nostril in the usual way, and a force indicated by the pressure of the mercury, plus the momentum of the blast, is expended in inflating the middle ears, and any surplus force, in place of working an over-distension of the drums, simply overcomes the upward pressure of the palate, and escapes into the pharynx. The instrument is called a Politzometer.

The report on necrology included the names of the late President, Dr. W. T. Kirk, of Atlanta; Dr. James S. Jewell, of Chicago; Dr. C. R. Hamill, of Chicago, and Dr. R. D. McArthur.

The Society adjourned until 9 a. m., Thursday.

THIRD DAY—MORNING SESSION.

The Society was called to order at 9:45 a. m., Dr. W. O. Ensign in the chair.

The president's address was referred to Committee on Publication without its presentation, on account of his illness and absence.

The report of the Committee on Publication was read by Dr. D. W. Graham. Three hundred and fifty copies of the transactions for 1886 were published at a cost of $348.96. Report was accepted.

Dr. J. W. Jones, of Danville, chairman of the special committee on "Diseases of Children," presented his report. He commenced by saying that he had sent out a circular-letter to a large number of physicians throughout the State of Illinois, in which he propounded the following questions:

1. Has there been much sickness amongst the children in your county or district during the past year? 2. What have been the prevailing diseases, and what has been the general type of such affections? 3. Have you had in your district any outbreaks of any of the contagious or infectious diseases of children? 4. Have you used in the treatment of children's disorders any new line of management seeming to give more favorable results than other plans previously adopted? 5. Do you believe the State Legislature ought to appropriate annually a sum of money sufficient to defray the expenses connected with investigations covering subjects embraced in infant mortality, its causes and reduction, and the contagious febrile diseases, their prevention and cure?

The numerous replies received showed an increase of sickness amongst children of about 25 per cent. Excepting the contagious and infectious diseases, the general line

of disease comprised bowel complaints during the summer, and respiratory affections during the winter, all influenced more or less by malarial toxæmia. With but one or two exceptions the contagious or infectious diseases prevailed somewhat extensively. Scarlet fever, German measles, diphtheria, and pertussis have been very prevalent. Most cases of German measles have lacked the alleged pathognomonic symptom, viz: the post-auricular glandular enlargement. Rheumatism has been very prevalent in both young and old. Dr. Jones expressed confidence in the phospho-iron preparations, and salicin, in the treatment of such affections. The last query was answered by nearly all in the affirmative.

Dr. F. J. Shipp, of Petersburg, read a short paper on

The Care of Children,

calling particular attention to cleanliness. No water-bath should be resorted to during the first twenty-four hours of extra-uterine life. The child, however, should be given an oil-bath, lightly covered with an article of apparel of some kind, and at the end of twenty-four hours a warm bath of short duration should be given in a warm room.

DISCUSSION.

Dr. E. Ingals: There is one point relative to the treatment of pertussis to which no reference has been made, and that is the use of chloral and morphia. The treatment is very simple. I confine myself almost strictly to it, and it is very effective in the later stages of the disease. I use one-thirty-second of a grain of morphia and one grain of chloral, and repeat, if necessary, in a child of three years old. In the diarrhœas of children I endorse the antiseptic treatment.

Dr. Robert Tilly, of Chicago: "There was one point in Dr. Jones' paper that I would like to see ventilated a little, and that is the matter dignified by the name of Skeer's symptom. I know but little about the sign, but have made repeated efforts to get as much information on the subject as possible. When the report was brought up before the Pathological Society of Chicago, a committee was appointed to investigate this particular sign, and, as I understand, at that time one case was referred to as being typical at St. Luke's Hospital. I made the best possible effort to see the case, but learned that the child had considerably improved and had left the hospital. This, I believe, was the only case that the committee had an opportunity of investigating. I refer to it, because I think too great importance has already been attached to Skeer's symptom. We have Argyll Robertson's symptom, which is well established, and it would be unwise for us to foist this supposed peculiarity upon the medical profession without a good deal more evidence than we have at present.

Dr. H. M. Moyer, of Chicago, remarked that he was responsible for the term "Skeer's symptom." At the time when the allusion was made, the committee did not have any cases of tubercular meningitis under their care, but they availed themselves of every opportunity and means to secure a case or two. There were, however, cases of doubtful tubercular meningitis, and in these cases the sign was absent. The case seen by Dr. Skeer at St. Luke's Hospital was pronounced a typical one by him.

Dr. C. W. Earle: There has been a great number of cases of measles, and an epidemic of German measles, also a few cases of varicella of a severity which he had never before witnessed. In a large number of the cases of German measles the post-auricular glandular enlargement was absent.

Dr. A. H. Foster, of Chicago: My experience has been that we have had a rather typical epidemic of measles; and following the cases of measles in three to six weeks there were many cases of German measles without the pathognomonic symptom alluded to. In several of these cases a longer stage of convalescence was present. I attribute this more to debility arising from the first attack than anything else.

Dr. G. W. Nesbitt; I have seen many cases of German measles; sometimes one or two members in a family had the post-auricular glandular enlargement, while in others of the same family it was absent; therefore, I think German measles may occur without the enlargement referred to by Dr. Earle.

Dr. John H. Hollister said that physicians of Chicago had seen more cases of measles than ever before during the history of the city.

Dr. E. L. Herriott, of Jacksonville: German measles in our town last year were light, but this year they have been severe and the epidemic pronounced.

Dr. A. E. Goodwin, of Rockford: I have seen many cases of German measles during the year, and very little treatment was necessary. I would like to know if there is a law requiring children to have a physician's certificate before returning to school after an attack of measles.

Dr. G. W. Jones, of Danville, agreed with

Dr. Shipp concerning the treatment of the new born, especially the oil bath. He had used the chloral and morphia treatment, but owing to its depressing effects, he abandoned it. He had observed cases of German measles without the post-auricular glandular enlargement.

Papers referred to committee on publication.

THIRD DAY—AFTERNOON SESSION.

The Society re-assembled at 2 p. m.

Report on Dermatology.

Dr. Henry J. Reynolds, of Chicago, presented his annual report in this department, dealing first with the

Treatment of Lupus Vulgaris by Electrolysis.

He said: This method of treating lupus vulgaris was suggested by Gärtner and Lustgarten in the *Wiener med. Wochenschrift*, Nos. 27 and 28, 1886. They used a flat metallic pad large enough to cover the lupus nodule, the healthy skin being protected by a rubber ring around the pad. This pad was connected with the negative pole of a galvanic battery, with a current of sufficient strength to produce an escharotic effect, which is said not to produce much pain. The nodule becomes immediately swollen, with a discharging surface. In a few hours it becomes depressed and covered with a brown scab. This is now to be dressed as an ordinary sore, with ointments, etc. In from eight to fourteen days the scab falls, and a smooth flexible scar is left.

In regard to this treatment, while it is without doubt a very good way of accomplishing the same result that is now produced by other means, it nevertheless must necessarily be just as far from a sure cure for the disease as the other methods—caustics, scarification, scraping, etc., from the fact that lupus vulgaris is a disease which almost always crops out sooner or later in places remote from the original nodules. I have under treatment at the present time a case which responds very readily to local applications to the nodules, which are more or less numerous; but when apparently cured, in due time fresh nodules crop out in other localities. In another case recently under my care, the disease, often resisting all local applications, responded promptly when a sulphate of magnesia laxative was given internally in conjunction with the local applications, a fact which only illustrates an old principle, viz, that fluxions, local congestions, etc, may nearly always be reduced by depletion through the alimentary canal, as in the case of acne, roseola, erythematous eczema, and other local congestions.

Urticaria and Pruritus.

In an article in the *Buffalo Medical and Surgical Journal* it is claimed that there is nothing equal to a two to ten grain solution of menthol for relieving the itching of these very annoying and stubborn affections; that it not only promptly relieves the itching, but seems to have a curative effect. While my own experience with the remedy is not sufficient to warrant a positive statement regarding its value, I am led to believe it to be one of the best, especially in pruritus ani, where camphor solutions and other stronger remedies are not always well tolerated. Where there is a tendency to eczema, however, as a complication, or a result of scratching in pruritus, I have never found anything better than camphor solutions, which I generally use in the form of the ordinary soap-liniment, as it not only relieves the pruritus, but has an excellent effect on the eczematous condition.

Lanoline.

This drug, though not a new one, has come into general use only during the last year, being first brought to the notice of the profession by German writers. It is a fatty substance obtained principally from the wool of the sheep. Medicinally inert in itself, it is used as a basis for ointments. For this purpose it has advantages and disadvantages as compared with other substances used for making ointments, such as lard, vaseline, etc. The advantage claimed for it is that it is more readily absorbed than most other ointment bases. It has the disadvantage, however, of having an offensive odor and being more expensive;* while in many cases vaseline, and substances not so readily absorbed, are preferable, inasmuch as when protection and soothing effect are desired the remedy least easily absorbed is more desirable. In the *Journal of Cutaneous and Venereal Diseases*, June, 1886, Dr. Geo. Henry Fox sums up his conclusions as follows: 1. Lanoline is more readily absorbed by the skin than any other fatty substance; 2. as a basis for ointments, it is useful when an effect upon the deeper skin or upon the whole system is desired; 3. on account of its firm consistency it is advisable to mix with it a certain amount of lard, especially in cold weather; 4. when applied to a highly inflamed skin, it may not prove as bland as fresh lard or pure vaseline; 5. considering its recent in-

[*Lanoline, as now prepared, is almost odorless and may be obtained at a very reasonable price.—EDITORS MEDICAL AND SURGICAL REPORTER.]

troduction, its questionable superiority, and its present cost, it cannot be recommended as yet as the best basis for all ointments.

Hot Vaginal Douche in Acne of the Female.

Dr. M. Hutchinson (*Medical Record*, May 28, 1886), acting on the suggestions originally made by Sherwell, of Brooklyn, of passing the sound in the male urethra, to which reference was made in my report on dermatology a year ago, proposes, for an analogous effect, the use of the hot vaginal douche in the female. He reports several cases which he claims were cured by this method.

Molluscum Fibrosum.

Dr. R. W. Taylor contributed two very exhaustive articles bearing upon the etiology, pathology, mode of evolution and retrogression of this disease, and regards the so-called dermatolysis as pathologically the same as molluscum fibrosum, and believes with Simon and Behrend that the latter and the so-called strawberry marks, pigmented nævi, warts, etc., are closely allied.

A New and Useful Instrument.

Dr. E. L. Keyes has described an instrument which he invented and which he calls the cutaneous punch. It is about three or four inches long, with a hole in the end similar to that in an ordinary punch, and with a sharp cutting edge defining the hole. He uses it to remove the stained specks of skin in the face due to gun-powder; also for corns and other small growths. To remove the gun-powder specks, he presses the punch with a rotary motion through the entire thickness of the derma and removes each piece. His results were satisfactory. In a case of corns he presses the punch down through the center of the growth, cutting out all the sensitive part of each corn. His results were good. A number of sizes, from $\frac{1}{16}$ inch up, are required.

Cocaine as a Local Anæsthetic.

Knowing that cocaine is not well absorbed by the skin, and therefore does not produce much of an anæsthetic effect, Dr. Wagner, of Vienna, was led to make experiments for the purpose of ascertaining a method by which a better absorption and anæsthesia might be produced. Basing his theory upon the established principle that fluids move from the positive to the negative pole in a galvanic current, he saturated the positive electrode with a cocaine solution, applied it to the skin, and applied the negative pole a short distance from the positive. As the result seemed satisfactory, he made a number of similar experiments in the clinic of Billroth to determine the value of the method in surgical practice. He found that by keeping the positive electrode saturated with a sufficiently strong solution, and allowing the current to pass in the manner described for a short time, incisions could be made in the skin without producing any pain. His results and the description of the method were presented to the Society of Physicians of Vienna at their meeting February 5, 1886.

In regard to this method, I may say that I have personally made a number of experiments with a view of ascertaining its merits, which I intend to publish soon in the form of a paper, but which would occupy too much time were I to report them here. I will merely say that in my hands the matter is a success, and in my opinion one of the most useful discoveries in dermatology which have been made during the year 1886. In my experience, in the operation for the removal of superfluous hairs by electrolysis, and in other minor operations on the skin, the patient need experience absolutely no pain whatever.

Dr. Seth S. Bishop, of Chicago, read a paper on

Operations for Mastoid Disease.

Surgeons agree that in all cases of confined accumulations of pus in the mastoid region free incisions should be made, the cavity drained and made aseptic. The incision should be made clean to the bone, from one-half to one inch in length, right over the mastoid tissue. The arguments in favor of the mastoid operation are, that in nearly every case good results have been obtained, while in no case have patients been made any worse.

Dr. F. Fletcher Ingals, of Chicago, read a paper on

Epistaxis,

prefacing his remarks by citing a few cases which came under his observation. Epistaxis may be simply the result of a local plethora. In old people the most frequent causes are degenerative changes in the blood-vessels. The treatment consists in arresting hæmorrhage, and preventing its recurrence. To arrest the bleeding, firm compression of the nostrils for ten or fifteen minutes should be resorted to. The application of cold is equally good. In more aggravated cases syringing out the nose with cold water and the subsequent insufflation of a powder containing four per cent. of cocaine, and a suitable preparation of iodoform, are highly

recommended. In alluding to plugging of the nares, Dr. Ingals said: "A piece of surgeon's gauze an inch in width, and four feet in length is thoroughly saturated in a solution of tannin prepared by rubbing sufficient in water to make a thin syrupy mixture. Opening the nostril with a speculum, one end of the slip is folded on itself and over the end of the probe by which it is carried quickly to the posterior part of the nasal cavity, and then fold after fold is passed slowly in until the cavity is completely filled. This plan has been successful in extreme cases of epistaxis."

Dr. Tilley was inclined to doubt that hæmorrhage occurring from the nose is usually an effort of nature to relieve plethora. He thinks it is rather an evidence of a weak point in the nose, and the physician should try to discover that point and apply a suitable remedy, if possible. Polypi are not infrequent in the young, as well as in adults, and as soon as noticed should be removed.

Dr. Liston H. Montgomery said a solution of dialyzed iron on absorbent cotton had been very effective in his hands.

Dr. H. A. Johnson, of Chicago, thinks the Paquelin cautery is very effective in the treatment of such cases. He does not place much confidence in the nitrate of silver.

Dr. Walter Hay reported on

Legislation for the Insane.

The subject was discussed at length by Drs. Kiernan, Cook, Hollister, Bridge and Davis.

Dr. Bridge moved the following, which was adopted:

"*Resolved*, That this Society heartily indorses the provision of the bill now before our legislature providing for the commitment of the insane in certain cases without trial by jury, and asks the legislature to enact these provisions at least."

Dr. Gray offered the following, which was adopted:

"*Resolved*, That the Illinois State Medical Society use all its efforts to secure legislation requiring the filling of all public offices having medical functions with medical men."

OFFICERS FOR 1888.

President—W. O. Ensign, of Rutland.

First Vice-President—Charles Warrington Earle, of Chicago.

Second Vice-President—P. H. Oyler, of Mt. Pulaski.

Permanent Secretary—David W. Graham, of Chicago.

Assistant Secretary—G. L. Eyster, of Rock Island.

Treasurer—Walter Hay, of Chicago.

Judicial Committee — A. Wetmore, of Waterloo; S. C. Plummer, and P. F. Crummer.

On motion the Society adjourned. Next place of meeting: Rock Island, third Tuesday in May, 1888.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

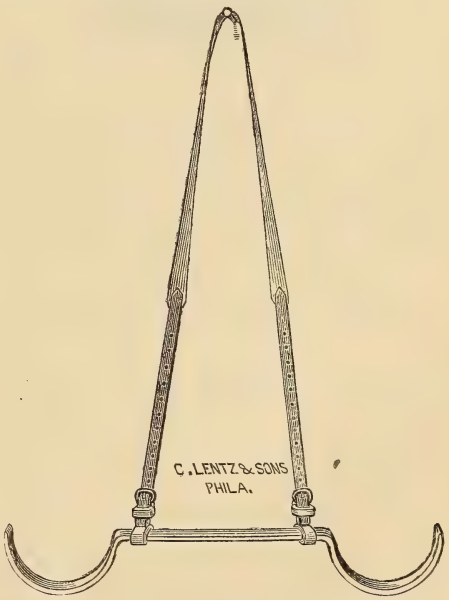
Stated meeting, May 11, 1887.

The Vice-President, E. T. Bruen, M. D., in the chair.

Dr. Thomas B. McBride described and exhibited

A New Apparatus for Maintaining the Lithotomy Position.

I desire to present to the Society this evening an apparatus I have designed for the purpose of supporting the limbs and maintaining the lithotomy position.



It consists of a piece of hard, elastic wood, preferably ash or hickory, $\frac{3}{8}$ of an inch thick, 1 inch wide, 36 inches long, bent at each end in a semicircle of 6 inches diameter, or a semicircumference of $10\frac{1}{2}$ inches, thus leaving a shaft of 15 inches between the semicircles, and making the length of the finished instrument 27 inches (6 + 15 + 6).

To the shaft, 2 inches from each end, a buckle is immovably fastened by means of leather.

A band of webbing, finished at each ex-

tremity with a leather strap, the whole 50 inches long, completes the device.

In using the apparatus, the thighs are flexed on the abdomen and put in the semicircles, the band is placed around the neck and fastened to the buckles.

The advantages are apparent. Its cheapness places it within the reach of every one. The thoroughness with which it does its work, keeping the patient immovably in the lithotomy position, and maintaining the same relative position of the parts; the fact that it does not interfere with the circulation; the strength, lightness, and remarkable simplicity, will, I think, render it a valuable acquisition to the surgeon and gynecologist.

Dr. Edward Jackson read a paper on

Determination of the Size of the Pupil.

The extent of the nervous connections which determine the contraction or dilatation of the pupil, and the variety of its reactive and correlated movements, make it an important index of many conditions of the local or general nervous system. But in all the accumulating volumes of loose medical literature, no symptom has been more loosely treated. Off-hand decisions of this matter, such as are commonly made, and their usual records "pupils dilated," or "pupils contracted," are at best worthless, and often misleading. They are made by reference to a mental standard or conception of what the average size of the pupil should be; which as a conception or understanding may be good enough, but which as a standard to test the case in hand is simply useless and deceptive.

The normal size of the pupil varies completely with the individual. In some normal eyes direct sunlight will not contract the pupil below five mm. in diameter; while in others darkness or even the strongest mydriatic will not dilate them to that extent. In one extreme case, Mrs. M., aged forty, who applied to the Polyclinic for relief from eye-strain due to hyperopia, and whose ocular and general health seemed in all respects good, the widest dilatation we could obtain with atropia or duboisia left the pupils less than two mm. in diameter.

Again, the size of the pupil varies with age—larger in the young, smaller in the old; causing in the latter really pathological dilatation to be overlooked, while the normal pupil of childhood is set down as "dilated." Then the knowledge that the pupil varies with exposure to light or with accommodation and convergence, though familiar to all of us, is too rarely applied in this connection.

With our present knowledge of the size of the pupil, and the conditions which influence it in health and disease, no examination can be regarded as fairly thorough and satisfactory which does not note—

1st. Its exact size when the gaze is fixed on a distant object, both in a bright light and in the weakest light in which it can be accurately measured.

2d. Its size when the eyes are fixed on some near object, as the finger held six inches in front of them. This should be measured by a weak light, unless the pupil is unusually dilated.

3d. Its behavior on covering the other eye with something which thoroughly excludes the light.

In an examination for ophthalmic purposes, of course, other matters are to be considered also. Each eye should be examined separately, and any inequality between the pupils especially noted. The report of such an examination should give exact dimensions, or at least the exact diameter of the pupil in a strong light, and other dimensions in their proportions to this, and not be couched in general phrases, which are, for the reasons above alluded to, well nigh meaningless. The bright light, referred to, is secured when the eyes are directed toward the the open sky in the middle of the day, or toward the flame of a student's lamp or common gas burner not more than ten or twelve inches distant. For the tests of weak illumination the source of light should be removed to one side of the eye, so that the rays may fall obliquely on the pupil. In this way fewer will enter it, and those which do, will fall upon a less sensitive part of the retina. Delay in the reaction to light, or its entire absence, are conveniently tested by observing the pupil through the ophthalmoscope at a distance of eight or ten inches, and (by turning the mirror) alternately leaving the eye in comparative darkness or flooding it with the concentrated light.

For accurately measuring the diameter of the pupil many little pieces of apparatus have been devised, the more important of which I have collected to show you this evening. One of the simplest devices, and a very serviceable one, is the scale of black circles or "pupils," proposed first, I think, by Follin, but more conveniently arranged by our fellow member, Dr. B. A. Randall. This scale is held close to the patient's eye, and the circle selected which most nearly matches the pupil in size, the diameter of this circle being given opposite it on the scale.

Fick proposed to measure the pupil sub-

jectively by means of two apertures in a black diaphragm which should be placed before the eye, one aperture being fixed, the other movable. Each aperture admits light to a certain circular area of the retina, the size of this area being determined by that of the pupil. Thus the appearance of two feebly illuminated circles is produced, and the distance between the apertures being varied until these circles become just tangent, that distance gives, with an easily obtained correction, the diameter of the pupil.

On this plan, Cretes* constructed his pupilometer, in which the distance between the apertures was made to vary by revolving a disk with a spiral linear aperture which intersected a fixed straight linear aperture; and Robert Houdin devised the other instrument here shown. This subjective method is superior to others in certain experimental investigations, but is of no importance in practice.

The pupil can be measured approximately by simply holding a finely graduated rule in front of it, and noting the number of spaces occupied; and various instruments have been devised to do this with precision. All of them, however, except that recommended below, are liable to the objection that the distance subtended on the rule is less than the diameter of the pupil in proportion as the distance from the observer's eye is less to the rule than to the pupil. This is shown in Fig. 1 by the dotted lines, the scale being represented by B B, and the pupil by C C; D D, although really shorter than the diameter of the pupil, seems to cover it.

A sort of "cross" between this method and the series of black circles is the scale of Mr. Jessop. You see it is a strip of metal, along the edges of which are cut out a series of semicircles of different diameters.

But for measuring the pupil, in the observation of cases, I think the best instrument is the so-called keratometer, devised by Priestley Smith, of Birmingham, England.† This consists of a scale placed between two plano-convex lenses. The observer's eye is placed about the principal focus of the combined lenses (ten inches from them), and holding the scale before the observed eye the cornea or pupil subtends on the scale exactly its proper length, whatever its distance from the scale, because rays converging to the principal focus of a lens system must have entered that system parallel.

This is illustrated by the solid lines of figure 1, A, where the observer's eye is placed,

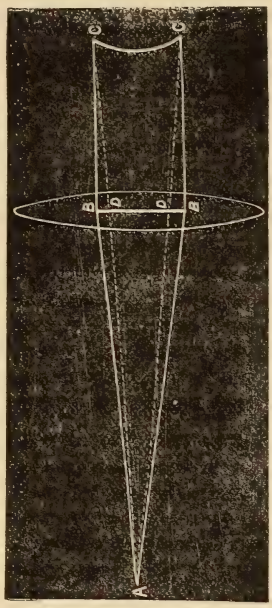


FIG. 1.

being a principal focus of the lens B C, and B C must be parallel; hence B B exactly equals C C no matter how far they are apart.

The equality or inequality in the size of the two pupils and abnormalities of shape

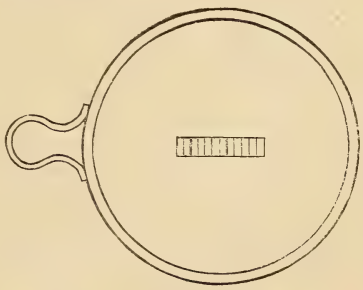

FIG. 2.

can be observed without special apparatus, though such apparatus has been devised. But it must be remembered that both inequality of the pupils and irregularity of shape are common anomalies of development.

Since the difficulty of determining the presence or extent of pathological alterations of the pupil rests on the lack of general conformity to any standard of size or reactions, any comparative observations on the pupils of the patient in health are of especial value.

* For full descriptions of these and other forms of apparatus, see Traité Complet d'Ophthalmologie, of De Wecker and Landolt, t. premier, pp. 942–953.

† See Ophthalmic Review, November, 1886.

The significance of the different conditions of the pupil, which may be observed, is outside the scope of my paper. Probably the best consideration of it is to be found in the chapter on that subject in Swanzy's text-book on *Diseases of the Eye.*

DISCUSSION.

Dr. George de Schweinitz said: I can endorse Dr. Jackson's criticism of the ordinary reports of the conditions of the pupil. It would be equally valuable in a case of cardiac disease to say simply that there was a murmur, as to describe the pupil in the vague terms usually adopted. I have had no experience with the instrument designed by Priestley Smith. Dr. Randall's instrument has given me complete satisfaction.

Dr. S. Solis-Cohen reported a case of

Asthma Treated by Bergeon's Method.

"By request of the Chairman of the Directors, I will briefly report a case of asthma in which immediate relief followed the injection into the intestine of the mixture of carbon dioxide and hydrogen sulphide, as recommended by Bergeon. Having noticed in Morel's paper reports of two cases in which success attended the experiment in one of the Parisian hospitals, and a case presenting itself which offered a fair test, I determined to make the trial.

"The patient is a stout married woman, about fifty years of age, of somewhat neurotic temperament, who has been subject for some years to attacks of spasmodic asthma, ordinarily manifesting recurrent paroxysms, lasting ten or twelve days. In the intervals there is neither bronchitis nor dyspnœa. There is no heart lesion. I have seen her in previous attacks, which have been relieved by methods with which we are all familiar. In one particularly obstinate seizure, by advice of Dr. J. Solis-Cohen, the patient was sent to the gas works, and was benefited by inhaling the carburetted vapors there produced. I saw her on the second or third day of the attack, and proposed the injections, but could not obtain her consent. Not wishing to complicate the therapeutics too much, in case she should later accede to the proposal, I simply prescribed, as a palliative for the dyspnœa under which she labored between the paroxysms, quebracho, in twenty drop doses of the fluid extract, repeated hourly or half hourly, according to indications. This, of course, gave great relief, but a paroxysm recurring in the evening, the patient consented to try the injection. Almost immediate relief was experienced. Some dyspnœa persisted, but there was no further paroxsm, and the dyspnœa gradually lessened, finally disappearing within thirty-six hours. After six injections, the later ones being prophylactic rather than therapeutic, the patient professed to feel better than for years, and auscultation revealed only normal breath sounds.

"This is, of course, but a single case; yet having a standard of comparison in previous attacks in the same individual, I can, so far as one case is worth anything, confirm Morel's claim that the rectal injection of carbon dioxide and hydrogen sulphide is beneficial in asthma. Which of the two gases is the active agent, and whether, or not, it would be equally efficacious by inhalation, are questions which I do not now desire to discuss."

THE NEW YORK NEUROLOGICAL SOCIETY.

Stated meeting, May 3, 1887.

Charles L. Dana, M. D., President, in the chair.

The election of officers for the ensuing year resulted as follows: For President, C. L. Dana, M. D.; for First Vice-President, W. R. Birdsall, M. D.; for Second Vice-President, M. A. Starr, M. D.; for Recording Secretary, G. W. Jacoby, M. D.; for Corresponding Secretary, W. M. Leszynsky, M. D.; for Treasurer, E. C. Harwood, M. D.; for Councillors, E. D. Fisher, M. D., B. Sachs, M. D., L. Weber, M. D., E. C. Seguin, M. D., and G. M. Hammond, M. D.

THE DISCUSSION.

Dr. R. L. Parsons' paper on

Nomenclature of Psychiatry,

read at the last meeting of the Society, was taken up (see the REPORTER, April 30, 1887).

Dr. Kellogg said he was not well informed of the contents of Dr. Parsons' paper, but he would say that it seemed to him the term monomania had come into so general use in literature, both medical and medico-legal, that it would be very difficult to get rid of it. It was very easy to use new terms, and perhaps etymologically they might be more appropriate than the old, but there was a practical use of the word monomania, and it was very difficult to find another which would fill its place. Monomania had been employed to indicate many different conditions of mental disease. If we could limit the clinical group of mental symptoms we might then suggest more exact terms. There was a group of clinical symptoms associated

with certain neuroses, such as epilepsy and chorea, also sometimes associated with toxic states, as in alcoholismus, or with diathetic states, as syphilis or tuberculosis, which took the form of a fixed delusion. By some authors, such symptoms had been classed under the term monomania. Other authors had applied this term to conditions of perverted emotions. What one term would better indicate all these conditions than the word monomania? He thought none. All that he could do would be to single out the several clinical groups of symptoms included under the term monomania, and apply to each group a distinct term. He thought, however, the generic term monomania would remain. At any rate, he could see no advantage in seeking for a new term which would replace it. If Dr. Parsons wished to designate one distinct group of symptoms from among several which were not included in the term monomania by the use of the term oligomania, he might agree with him, but he did not think any advantage would be derived from substituting the latter term for the former.

Dr. W. R. Birdsall had listened with interest to Dr. Parsons' paper on nomenclature in psychiatry because of the importance and difficulty of the subject, but the impression left upon his mind was that we were not much better off with the terms coined in recent times. He must certainly agree with the author regarding the indefiniteness with which the term monomania had been employed, but he agreed with Dr. Kellogg that in its generic sense it was pretty well understood. There was, however, a popular misconception regarding its meaning which he thought constituted a strong objection to its use. Dr. Birdsall had come to use the term paranoia as a substitute for that of monomania with satisfaction to his own mind. The objection to it mentioned by Dr. Parsons, that it did not mean much if anything, in Dr. Birdsall's opinion constituted one of its merits. Monomania was so definite as to be liable to misconstruction. In reconstructing nomenclature he sometimes thought that it was a misfortune that we could not fall back on Choctaw instead of being compelled to resort to Greek or Latin. There was a certain disadvantage in having to resort to a compound word to express a group of symptoms or type of disease; it often failed to describe anything clearly. He believed with Dr. Kellogg that unless the symptoms included in the general term monomania were subdivided into groups, and an appropriate term for each group was found, little advantage would be derived by substituting a single new term.

Dr. B. Sachs objected to the term monomania for two reasons; First, Its etymological meaning was different from its accepted meaning in the nomenclature of psychiatry; Second, In accepting its use, we implied our approval of the old division into monomanias, and thus lost sight of the true character of serious mental troubles. He thought the term oligomania was less objectionable than that of monomania, but he did not believe there was any absolute need of either term at the present time. He had not been compelled to make a diagnosis of monomania for several years. In general he agreed with Dr. Birdsall's remarks on paranoia, but he thought the term primary insanity would be little liable to misconstruction, and might on some grounds be preferred either to paranoia or monomania. He would be in favor of using the term paranoia or primary insanity with such qualifying phrase as to character of delusions, etc., as might be necessary in different cases.

The President thought Dr. Parsons deserved credit for his paper, as there was certainly need of improvement in our nomenclature. If the paper had been read five years ago the term oligomania would probably have stood a better chance for adoption. But it had now become fashionable to use the word paranoia, and he, like Dr. Birdsall, felt a certain amount of mental satisfaction in its use. He had some time since come to the conclusion that any attempt to reform nomenclature, if by a single individual, would be utterly useless. Such questions must be referred to conventions. One man could do nothing unless he discovered some fundamental principle on which to base a nomenclature which would prove superior to that now in use.

Dr. Parsons thanked the members for the adverse, as well as the favorable criticisms of his paper, and in reply repeated certain statements made in his paper. He did not believe that any convention of men could alter a nomenclature. Whether or not a given term would be adopted, depended much upon accidental circumstances. He looked for advances in nomenclature rather from individual effort. He had not found it necessary to use the term monomania; the term partial insanity was far more applicable in many cases.

Cerebral Tumor—Partial Removal.

Dr. S. N. Leo read the history of a case of cerebral tumor occurring in a heavy German

woman who had, before its appearance, sustained an injury of the skull where the tumor afterward developed. During the growth of the tumor the patient had consulted several well-known physicians, all of whom were of the opinion that an operation should be performed. Some thought it was a wen of the scalp. The symptoms becoming more serious, she finally asked Dr. Leo to perform the operation. He was assisted by Dr. Harwood and Dr. Guleke. Strict antisepsis was observed. As the operation proceeded it was found that the tumor extended within the cranium, involving the dura mater at the longitudinal sinus, and apparently dipping deeply into the brain substance. These facts in addition to the patient's bad condition from loss of blood led him to desist from further procedure after cutting off that portion of the tumor external to the cranial vault. He thought the patient would not have lived so long—over a month—had not the operation been performed. Unfortunately an autopsy was not allowed. The tumor was a sarcoma. He added that the patient's condition had been rendered more serious by cardiac disease.

Dr. L. Weber regretted that the title of the paper on the cards of announcement had been "Report of a Case of Cerebral Tumor —successfully removed." He also regretted that there had not been a post-mortem examination.

Dr. B. Sachs then read a paper entitled

Notes on the Cause and Treatment of Functional Insomnia.

Under this term he included cases of insomnia, pure and simple, occurring in persons of the neuræsthenic habit. He preferred to say neuræsthenic rather than hysterical, for in his experience actual insomnia is less frequent in truly hysterical patients than in those suffering from cerebral or spinal neuræsthenia. A number of typical cases were given. In attempting to explain these cases, and referring to work done by physiologists on this head, the reader concluded that in the majority of cases there was good evidence of disturbances in the cerebral circulation. And, as Morro had found in animals that increased activity of cerebral circulation was accompanied by deficient circulation in the peripheral organs, so in many cases of chronic insomnia, cold extremities, pallor of the skin, scanty uterine flow pointed to deficient peripheral circulation, and in many of these cases there were weak heart and weak pulse. Special attention was called to the simultaneous occurrence of insomnia and headache, and to the fact that in these cases the headache was, as a rule, of the paralytic migraine type. Cases were quoted in evidence.

The treatment in cases of migraine and insomnia was similar in many respects, and proved effectual in both conditions.

Dr. Fisher thought a very common cause of insomnia was anæmia, and he had seen considerable success in its treatment by cod-liver oil, cream, and articles intended to improve nutrition; in some of the cases ordinary hypnotics had been administered without any avail. The patients might have the appearance of being well nourished while they were really anæmic. The mineral tonics were as a rule indicated.

Dr. George W. Jacoby thought the paper was an exceedingly important one, especially in that it called attention to the fact that many cases of insomnia could be cured by rational measures alone, without the use of any medicines whatever. He agreed with the author that the cases must be individualized, and thus the cause of the wakefulness might be discovered. He thought that in the majority of cases the cause would be found to lie in the circulation—not always in anæmia, but frequently in hyperæmia. Cure the cause and we would cure the sleeplessness; but that which would cure anæmia in one case would not cure it in another. Active and passive exercise, particularly active exercise, were of benefit. For patients who could not go out, the muscle-beater was very useful. While he had not much faith in static electricity in the treatment of insomnia, he cited one case in particular in which the physician who applied it for another purpose to one of his patients, himself became sleepy under its influence. Perhaps the production of ozone by the instrument was the cause of this sleepiness, for it was well known that when we went into an atmosphere of ozone we were likely to become sleepy.

Dr. V. P. Gibney had noticed that static electricity had tended to produce the sleepy state. It was one of the few things they had found static electricity good for at the hospital with which he was formerly connected.

Dr. W. R. Birdsall thought, as did Dr. Sachs, that we must adopt hygienic rather than purely medicinal measures for the cure of insomnia, but we were occasionally forced, as the author had said, to resort to some drug for temporary relief. For this purpose he had obtained benefit without injurious effects, such as sometimes came from bromine, hydrate of chloral, etc., from a drug first

recommended to him by Dr. Seguin, namely conium. This given in large doses, fifteen or twenty drops or more, of the fluid extract, had in his hands been beneficial. He had continued its use two or three months without deleterious results.

Dr. G. M. Hammond thought fully eighty per cent. of all his patients were similar to those described in the paper by Dr. Sachs —persons suffering from insomnia, mental anxiety, etc. In the large majority of the cases he thonght it was due to hyperæmia of more or less limited areas of the brain. When the patients did sleep they had unpleasant dreams. They were also frequently sufferers from dyspepsia, constipation, spots before the eyes, noises in the ears, sometimes hallucinations connected with various senses, and coldness of the extremities. It was rare for such patients to go away without being cured, but if they subjected themselves to the same causes the condition returned. He used bromides and stuck to them right through the disease. He gave only ten or fifteen grains three times a day, and also gave fluid extract of ergot. He applied static electricity and dry cups to the back of the neck, and regulated the sleeping hours.

Dr. Leszinsky was rather surprised, in view of a recent discussion before the society, to hear Dr. Sachs speak of the use of hyoscyamine as hypnotic. It was a mistake to rely upon large doses of bromides given at night. There was an objection to their use by ladies because of the bad odor which they gave the breath. He had not been able to discover any peculiarity in the circulation of the retina in these cases.

Dr. L. Weber said that since he had adopted the treatment recommended by Dr. W. A. Hammond, and just described by Dr. G. N. Hammond, he had obtained the best results in cases suitable for this mode of treatment, but in other cases the bromides might cause excitement instead of aiding sleep. When there was gastro-intestinal disorder, he added calomel to the treatment with benefit.

Dr. Leszynsky referred to a remark by Dr. Birdsall concerning the use of a mustard sinapisms, or other cutaneous irritants, and said that Dr. N. H. Thomson had called attention to the beneficial effects of cayenne pepper, etc., to the surface of the body some years ago.

The President had found the warm bath a very valuable measure in many cases; in mild cases of insomnia the could doucne down the back, and massage, had proven useful. Bence had discovered that ozone had a hypnotic influence. Lupulin had been of benefit in the insomnia of old people; and lavender in some cases in which the stimulus of alcohol or warm food had failed.

Dr. Sachs objected to the use of the bromides, particularly in small doses, more than to anything else in the treatment of the class of cases under discussion, namely, those of insomnia in neurasthenic subjects. It was likely to do more harm than good. The testimony, in the discussion referred to by Dr. Leszynsky, was not against amorphous hyoscyamine, but against the crystalline form.

The President exhibited

An Apparatus for the Relief of Writer's Cramp,

called the "kaligraph" by its inventor, the late Mr. Charles Thurber. It consisted of an iron frame-work, to which was attached a series of levers so arranged that by making large characters at one angle the characters were reproduced in ordinary size at the opposite angle. It was, in fact, a kind of reversed pantagraph. Dr. Dana said that all writer's-cramp instruments were based on the principle of resting the groups of muscles most used, and throwing the work upon other groups. The kaligraph fulfilled these indications better than any other instrument with which he was familiar. The objections to it were that it was cumbersome and expensive. The speaker showed cuts of all the various forms of instruments for writer's cramp (ten in all) which he had been able to collect. The kaligraph had been in practical use for thirty years, but it was very little known. It had enabled its inventor, who had suffered extremely from the cramp, to write with comfort. He was informed that Mr. Charles Dickens had possessed and used one.

Dr. G. S. Jacoby thought this instrument was only palliative, while Nussbaum's was also curative, and could be carried with one. It compelled the writer to use the abductors.

The President replied that an instrument calling into play another group of muscles of the hand would cause those to be affected after a time.

Dr. Birdsall thought writer's cramp was due to cerebral fatigue rather than to muscular fatigue, and that instruments for overcoming it could be of only limited benefit.

—Another occupation is to be improved for men. Bellevue Hospital, New York, is promised a training school for male nurses—a rich Californian having given $80,000 towards putting it on a solid footing.

EDITORIAL DEPARTMENT.

PERISCOPE.

On the Administration of Carbonate of Lime as a Means of Arresting the Growth of Cancerous Tumors.

Nearly twenty years ago Dr. Peter Hood published in the *Lancet* a communication on the value of carbonate of lime, in the form of calcined oyster-shells, as a means of arresting the growth of cancerous tumors, and in that journal for May 7, 1887, he says: "I am anxious once more to call attention to the subject, and to urge upon those who possess the necessary facilities that a more extended trial should be given to this agent than it appears yet to have received. My own opportunities of employing it in suitable cases have not been large, but the results which I have witnessed have been sufficiently remarkable to justify me in seeking for them a more extended publicity.

"In the paper referred to, I related in detail the case of a lady nearly eighty years of age, who was the subject of scirrhus of the breast, and in whom the growth sloughed away and left a healthy surface after a course of carbonate of lime, administered in accordance with a recipe which was current in her family. She manufactured her carbonate of lime by baking oyster-shells in an oven and then scraping off the calcined white lining of the concave shell. The substance thus obtained was reduced to powder, and as much as would lie on a shilling was taken once or twice a day in a little warm water or tea. It was said that perseverance for at least three months was necessary before any good result was to be expected.

"The immediate cause of the publication of my paper was a conversation with Mr. (now Sir) Spencer Wells, to whom I related the particulars of the case above mentioned, and of one or two others which had fallen under my notice, and who suggested that the beneficial action of the powder might be due to the lime which it contained. He told me that he had used lime largely in the treatment of uterine fibroids and other tumors, and that he was convinced that processes of atrophy and calcification, resembling the spontaneous change or degeneration sometimes observed in them, were often produced or promoted by its action. He added that he believed the change commenced in the coats of the arteries by which the tumors were supplied with blood, and that these coats underwent first an atheromatous and subsequently a calcareous degeneration, in either case with a diminution of the calibre of the vessel and a lessened capacity for the conveyance of blood.

"After the appearance of my paper I was applied to by several persons with an inquiry as to whether their cases were suitable for the employment of the remedy; but in most of these instances I subsequently found that it had been taken for only a few weeks and then abandoned because no result was apparent. I should not hope for manifest benefit in any instance under three months of persistent treatment. A notable exception to the ordinary want of perseverance was furnished by the wife of a physician practicing at Reading. This lady was the subject of a well-marked scirrhus of the breast, which I had myself an opportunity of examining. After a fair and persistent trial of the calcined shell powder for three months, her husband reported to me that 'the tumor had ceased growing, and that she suffered no pain.' She continued to take the powder for several months longer, and for several years her husband paid me an annual visit, always giving the same account, 'that his wife never suffered any inconvenience or pain from her disease, the progress of which had been stopped.'

"The ordinary history of true cancer is such a dismal record of failure, that I think even a few instances in which benefit has been derived from a harmless remedy should encourage the profession to make a trial of it in all suitable cases. It would probably be inexpedient, generally speaking, to disclose the nature of the medicine, and the public mind is by degrees becoming permeated by the knowledge that many important medical actions can only be gradually produced. We have no difficulty in inducing patients to submit to prolonged courses of mercury in the treatment of syphilis, and there is no reason why they should not do the same in a malady which, if possible, is even more formidable. Up to the present time the narratives of cures of cancer have been chiefly suggestive of errors of diagnosis, and no assurance of the value of any proposed remedy can be obtained until it has been used in a sufficient number of instances

to exclude the possibility of such errors having been committed in the majority of them. Although the experience of Sir Spencer Wells with fibroids points to the probability of a beneficial action upon soft and vascular growths, those which I should myself select for the purpose of further investigation would be typical examples of breast scirrhus, adherent tumors of stony hardness, attended by retraction of the nipple and lancinating pain. About the nature of such, it would seldom be possible to entertain a doubt.

"It is therefore not in cases which admit of any reasonable doubt of their nature that I would desire to urge a trial of the lime powder upon the profession. There are hundreds of instances of unmistakable cancer in which an operation, if performed, may perhaps for a time diminish suffering or may prolong life, but in which it cannot afford any well-grounded hope of restoration to health. For all such I would say that the lime ought to be persistently and fairly tried. It can do no possible harm, it need not interfere with any remedies for the present relief of pain, its action can be referred to a perfectly intelligible and probable hypothesis, and it has been of unquestionable utility in a sufficient number of cases to warrant us in reposing some confidence in its use. We have a great hospital devoted to cancer, and cancer wards in others also; and I think the time has come when this simple means should be fairly tested by the profession. It is not long since we witnessed an extraordinary eagerness to try the Chian turpentine, which was so much extolled by Dr. Clay, and in support of which the *prima facie* case was nothing like so strong as that in favor of the remedy to which I desire once more to call attention."

The Casualties Chargeable to the Employment of Antiseptics in Surgery.

The above is the title of a thesis for Fellowship by Dr. F. Brun, from a summary of which by A. Chevallereau in *La France Medicale*, No. 143, the following abstract is taken: The antiseptics which M. Brun has more particularly studied are phenol, iodoform, and corrosive sublimate. The casualties chargeable to phenol he divides into local and general; amongst the former is erythema, with or without pyrexia, and not unfrequently with vesicles, occasionally followed by eczema. The general casualties are phenol intoxication, characterized by dark urine, violent cephalagia, nausea, followed by vomiting; in severe cases the cerebral symptoms predominate, collapse, coma, convulsions, extreme pallor of the skin, sweating, coldness of the extremities, and a lowering of the body heat generally; paralysis of the bladder is not unfrequently present. In sulphate of soda the author thinks we have the most useful antidote for phenol, especially if given when the symptoms first present themselves. Iodoform also produces local and constitutional troubles; amongst the local annoyances are erythema, eczema, and erysipelas; amongst the constitutional troubles are gastric pains, anorexia, and a curious trouble, first noticed by Poncet (of Lyons), that the use of a silver fork or spoon by a patient using iodoform causes an iodoform and silver compound to be formed, which has a particularly fœtid smell, which can be made evident by rubbing the silver. To the gastric troubles are superadded nervous ones, insomnia, and nocturnal delirium. During the day the delirium may disappear and the patient became apathetic, and finally suffer from melancholia. Occasionally an eruption resembling scarlatina rash results. The temperature generally remains normal; the pulse, however, becomes diminished in force and increased in frequency. In the most severe cases, after nights of maniacal excitement, it is unusual for the patient to return to his usual quiet state the following day; but the headache continues, the intelligence is obscured, memory fails, and the embarrassment in speaking almost amounts to aphasia. Kœnig has noticed in severe cases of iodoform poisoning a comatose condition and also meningitis. In a recent number of the *Medical Press* a case of intestinal irritation, accompanied by severe purging caused by iodoform dressing is recorded. To combat the effects of the poison, Behring recommends a watery solution of 5 to 10 per cent. of bicarbonate of potassium. Casualities from the use of corrosive sublimate are of two kinds, that resulting from its external use and that as an internal medicament. The edges of the wound not unfrequently become inflamed, as do mucous membranes that are long in contact with corrosive solutions. Vesication of the skin sometimes occurs, and occasionally a rash of a bright red color. From its absorption stomatitis, sometimes very severe, albuminuria, hæmaturia, nephritic pains, cephalalgia, intellectual sluggishness, and bleedings from nose or mouth. In succeeding chapters of the monograph casualties resulting from the use of biniodide of mercury, subnitrate of bismuth, boracic acid, salicylic acid, alcohol, chloral, and the iodide and chloride of zinc are detailed.—*Medical Press and Circular, May* 4, 1887.

On the Value of the Hemorrhage in the Treatment of Wounds.

Professor Turazza, in the *Gazetta degli Ospitali* of April 13, publishes a note showing that hemorrhage from wounds, when not due to the lesion of large vessels or carried to excess, is of small importance, and does not interfere with primary union. He believes that the rule generally laid down regarding the first dressing of a wound—viz., to secure complete arrest of hemorrhage and to apply firm compression—though excellent, is not important. Professor Turazza relies on perfect disinfection of the bleeding surface, as far as within reach, by means of weak solutions of phenic acid, or corrosive sublimate. He then leaves the cavity of the wound full of blood, without any doubt as to primary union, the edges of the wound being very accurately sutured. As the result of his experience he formulates a new rule in surgery—"that in wounds perfectly disinfected and free from foreign substances, the effusion of blood is not a source of danger, but the reverse; for the extravasated blood fills up the cavity of the wound perfectly, preventing the formation of empty spaces, and rendering both compression and drainage superfluous, and, further, the organization of the clot favors healing." Professor Turazza also expresses himself as decidedly averse to the use of the drainage-tube, because it increases septic risks, and may remove from the cavity into which it is inserted fluids which in an aseptic condition may be useful by reabsorption. He advises the restriction of the use of the drainage-tube within the narrowest limits, and would deprecate its use even in ovariotomy, hysterectomy, and amputation of the breast, thinking it more dangerous than useful.

This is practically the method advocated by Schede, of Hamburg.

Creasote for Phthisis.

Fraentzel, of Berlin, has been using creasote in the treatment of phthisis since 1877, and has obtained excellent results where the treatment was begun early in the history of the disease. Patients far advanced in phthisis do not get much benefit from it. When it is beneficial the appetite and weight increase, and the expectoration diminishes. The formula used by Fraentzel is as follows:

℞.	Creasoti,	gr. xxvij.
	Tr. gentian,	f. ʒ j.
	Alcohol,	f. ʒ j.
	Vin. xeric, q. s. ad.,	f. ʒ iv.

M. Sig. — A dessertspoonful twice or thrice daily in a glass of water.

In our last issue we called attention to the use of creasote in phthisis, and to the plan of Sommerbrodt, who gives it in capsules. This plan we believe better than that of Fraentzel, who gives the creasote in solution, and rather too large a dose of it. We can speak from experience of the benefits which may be derived from the use of a pill, or "cachet," containing one grain of creasote and three or four grains of aromatic powder. This may be expected to be well borne by the stomach, and to benefit a patient not too far gone in phthisis.

A Terrible Lesson.

The *Journal d Hygiène* contains an account of the effects upon several children of Paris from eating some of the bitumen used to repair the streets. A child named F——, 13 years of age, had picked up a bit of the semi-liquid bitumen, and having made it into pills, he swallowed one, and tried to get other children to do the same, saying that it was good for the health, and "better for a cold than the best lozenges." His comrades followed his example; some sucked the bitumen, others ate a certain amount. The unfortunate F—— was the first victim. He went home with frightful pain in the stomach, and headache, and died in two days, without confessing to his parents the cause of his illness. His physician had diagnosed the case as one of meningitis. Another child had a severe illness as a consequence of his imprudence, from which, at date of writing, he seemed destined to recover. Others still, having told their teacher of their escapade, recovered from a temporary sickness after energetic emetics had been given them.

Nomenclature of Skin-Diseases; with Especial Reference to Hybrid, Syphilitic, and Medicinal Eruptions.

In an address thus entitled, Dr. Robert Liveing presents the following conclusions:

1. When two skin-diseases coëxist, they are generally quite distinct, and should be called by their well-recognized names.

2. That diseases are not natural, and do not follow the laws of natural development.

3. That it is very doubtful whether hybrid or crossed diseases exist at all, and that certainly there is no sufficient justification for a hybrid nomenclature.

4. That syphilitic skin-diseases differ from ordinary skin-diseases in their etiology, pathology, and treatment; and that this difference should be fully recognized in our nomenclature.

5. That medicinal rashes are not diseases of the skin, but simply eruptions, and should be so named.

Worms in Hens' Eggs.

In the *Monatschrift zum Schutze der Vogelwelt*, Professor Liebe adduces reliable data in answer to the question whether living worms are to be found in hens' eggs. A short time previously his sister had found a round thread-like worm, the length of a little finger, in the white of an egg. It moved itself in a very lively manner. She at once took the white of the egg to a druggist, who put the worm in alcohol. Professor Möbius, of Kiel, decided that the specimen was an example of the thread-worm of fowls—*Heteratis inflexa*—often found in the small intestine of the domestic hen. Only a few instances of the existence of the same in the white of the egg have been recorded.—*Allgemeine Medicinishe Central-Zeitung, April* 7, 1887.

Curability of Tubercular Meningitis.

In the *Revue Internationale des Sciences Médicales*, Dr. E. Martel has gathered notes of eight cases of tubercular meningitis cured by the inunction of iodoform. Five of the cases are recorded by Dr. Worfvinge (Stockholm), who speaks very hopefully of this treatment. All his cases evidently were meningeal, but it is not equally clear that all were tubercular. Besides adopting the usual internal remedies, he orders the head to be shaved, and inunction of 1 gramme of iodoform in 5 grammes of vaseline, to be made night and morning; 2 grammes of iodoform are thus rubbed in daily, and considerable irritation of the scalp frequently follows. After inunction, the head is covered with a light waterproof cap. In five cases, inunction was carried on for 17, 19, 30, 32, and and 9 days respectively.

Treatment of Neuralgia by Chloride of Methyl.

At the Societé Medicale des Hopitaux, M. Debore said that since 1884 his treatment of neuralgia by the chloride of methyl method embraced numerous cases. Over 150 persons suffering from sciatica were almost all cured instantaneously. He did not succeed so well in lumbago. Great prudence should be observed when the patients were diabetic, albuminuric, or very fat, and where there was œdema it should not be tried. After the application of the chloride of methyl, the skin remains permanently pigmented, so that where the face is concerned, the operation should be very quickly done and repeated.

The Work of Continental Hospitals.

The following statistics are taken from the article on the subject by Dr. E. Raseri in the *Revista della Beneficenza Publica:*

States.	Number of Hospitals.	Patients Cured.....	Deaths.....	Proportion of sick to 1000 inhabitans.	Deaths in 1000 treated.....
Italy.....	1192	307,085	38,431	12	111
France	1198	359,810	41,041	11	102
Germany	2109	506,045	42,579	12	79
Austria	549	227,315	28,704	12	112
Sweden	112	35,568	2,600	8	68

Cities.	Patients treated.	Proportion per 1000 inhab.
Rome.....	26,847	84
Paris	110,345	50
Berlin.....	43,551	36
Vienna.....	51,537	73

Ice in Post-partum Hemorrhage.

Several cases in which post-partum hemorrhage was successfully stopped by the introduction of pieces of ice into the uterus have been followed by symptoms of septicæmia. This fact, taken in conjunction with the recent researches of Prudden as to the presence of living bacteria in ice, may perhaps point to direct septic infection from the use of ice. Under any circumstances, hot water is probable preferable as a hemostatic agent, and the possibility of conveying septic germs in ice thus brought forward is another and still stronger argument against the employment of the latter.

Death Following Internal Urethrotomy.

Internal urethrotomy is so seldom followed by untoward results that the case reported by M. Jobard to the Surgical Society of Paris at their meeting on the 23d of February, 1887, is of much interest. M. Jobard performed internal urethrotomy for a traumatic stricture, and the case presented no unusual incident, except a rather free bleeding. The evening of the same day he was recalled to see his patient, who was dying, death resulting that night.

Remarkable Deformity of the Clitoris.

In the meeting of the Vienna College of Physicians, April 1, Friedinger described a case of extreme abnormality of the clitoris. The patient was a nurse in the Foundling Hospital; the clitoris was as long as one's

thumb, had a prepuce, and at the extremity, where the glans penis is normally located, there was an opening through which the urine was voided. Beside this, and a little behind, was the urethra in its normal position. The long clitoris had the appearance of a virile organ hanging over the ostium vaginæ.—*Allgemeine Medicinische Central-Zeitung, April* 13, 1887.

Fistula, Urethro-vesical Vaginal.

M. Pozzi, in the Surgical Society of Paris, narrated a case of successful operation for urethral vesical vaginal fistula in a patient who had been unsuccessfully operated on eleven times in the preceding eleven years. He ascribes his success to the use of the American Urethral forcing method.

Reviews and Book Notices.

BOOK NOTICES.

Healthy Homes and Food for the Working-Classes. American Public Health Association. Lomb Prize Essay. By Victor C. Vaughan, M. D., Ph. D., Professor in University of Michigan.

Manual of Practical Pharmaceutical Assaying, including Details of the Simplest and Best Methods of Determining the Strength of Crude Drugs and of Galenical Preparations. Designed especially for the use of the student and of the practical pharmacist. By A. B. Lyons, A. M., M. D. Detroit: D. O. Haynes & Company, publishers, 1886.

An admirably compact and practical treatise.

Does the Present State of Knowledge Justify a Clinical and Pathological Correlation of Rheumatism, Gout, Diabetes, and Chronic Bright's Disease? By James Tyson, M. D.

Nasal Reflexes as a Cause of Diseases of the Eye. By W. Cheatham, M. D.

Uterine Fibro-Myoma Complicating Delivery. Tumor Enucleated; Child Living; Mother recovered. Service of E. J. Beall, M. D., Fort Worth, Texas.

Miscellaneous Papers Relating to Anthropology. From the Smithsonian Report for 1885.

The Vest-Pocket Anatomist (founded upon Gray). By C. Henri Leonard, A. M., M. D., Professor of the Medical and Surgical Diseases of Women in the Detroit College of Medicine. 13th Revised Edition, enlarged by Sections on Anatomical Triangles and Spaces, Herniæ, Gynæcological Anatomy and Dissection Hints. Detroit: The Illustrated Medical Journal Co., 1887, cloth, 86 illustrations, 154 pages, post-paid, 75 cents.

The Physician's Dose and Symptom Book. By Joseph H. Wythe, M. D. Seventeenth Edition. Philadelphia: P. Blakiston, Son & Co., 1887.

Transactions of the Association of American Physicians, First Session, Washington, D. C., June 17th and 18th, 1886. Francis Delafield, M. D., President; James Tyson, M. D., Secretary; James P. Whittaker, M. D., Recorder. Philadelphia: Dornan, Printer, 1886.

Elementary Microscopical Technology. Part I. The Technical History of a Slide. By Frank G. James, Ph. D., M. D. St. Louis Medical & Surgical Journal Co., 1887.

The Lomb Prize Essays are published by the American Public Health Association, and may be obtained at cost price, separately or in a bound volume, by addressing the Secretary of the Association, Dr. Irving A. Watson, M. D., Concord, N. H. The titles of the essays are as follows:

I. "Healthy Homes and Food for the Working Classes." By Victor C. Vaughan, M. D., Ph. D., Professor in University of Michigan.

II. "The Sanitary Conditions and Necessitities of School-houses and School-life." By D. F. Lincoln, M. D., Boston, Mass.

III. "Disinfection and Individual Prophylaxis against Infectious Diseases." By George M. Sternberg, M. D., Major and Surgeon U. S. Army.

IV. "Preventable Causes of Disease, Injury, and Death in American Manufactories and Workshops, and the Best Means and Appliances for Preventing and Avoiding Them." By George H. Ireland, Springfield, Mass.

The Claim of Moral Insanity in Its Medico-Legal Aspects. By James Hendrie Lloyd, M. D.

Does Pulmonary Consumption tend to Exterminate the American Indian? By Thomas J. Mays, M. D.

An Experimental Inquiry into the Chest Movements of the Indian Female. By Thos. J. Mays, M. D., Philadelphia, Pa. Read before the College of Physicians (Phila.), April 6, 1887.

THE
Medical and Surgical Reporter.
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 *reprints will be furnished, in place of payment, if a request is sent with the manuscript. Contributors should* ALWAYS *state which form of remuneration they desire: reprints, extra copies of the* REPORTER, *or cash.*

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER will be published in each number. The regular edition for this week is 5,500 copies.

The editions of the REPORTER for May 7th and May 14th are exhausted, and orders are on hand for over one hundred copies of each. We will pay ten cents for each of these numbers, or, if any subscriber does not file his REPORTERS, he will place us under obligation by sending these numbers, and we, in return, will increase the duration of his present subscription two weeks. The address printed on the wrapper of the REPORTER gives the date to which each subscription is paid up, and the change in this date will indicate receipt of REPORTERS by us.

THE INTERNATIONAL MEDICAL CONGRESS.

We notice that the editor of the *Berliner klinische Wochenschrift* advises its readers to decide upon going to the next Medical Congress or not, according to their own wishes or their regard for the opinion of friends—presumably in America.

This advice throws a responsibility upon the medical men of this country which some of them may find it somewhat embarrassing to meet. Their attitude towards the Congress in the past has been one of active or passive opposition, and, although they might desire the success of the Congress, as a Congress, their abiding convictions, or their ideas of consistency, may prompt them to maintain towards this Congress the attitude which they have assumed. This is a state of affairs which we heartily regret, and we wish to do anything we can to better it.

Our view of the matter is this: Whatever differences of opinion there may have been in the past, whatever feeling of private wrong or of public error may still exist, patriotism and good sense demand that we should all strive to make the Congress a success. To oppose it now can only serve one end—to demonstrate that one-half of our country cannot do without the other. But who could desire to push this to a demonstration? We trust that, while the world lasts, no part of this country shall ever be able to be without any other, in politics, in science, in industries; that East and West, North and South, shall be inseparable in all good things. At present there is only too much evidence of the injury to all which is brought about by dissension. The credit of the country has been injured by the discord which has existed in regard to the Congress, and if those who thought it was wrong to array one section of the country against the other, and those who thought there was just ground for offence and retaliation, are not much wiser to-day than they were two years ago, then experience has failed to do its usual work. Both sides in this unfortunate controversy must now see how hasty action makes a difference worse, and that only calm forbearance and mutual concession can mend it. At the present moment he who feels most in the right can afford to show himself most conciliating, and we believe that all who have the future welfare of the country and the true glory of the profession at heart may and should dismiss the past and unite with those from whom they have been for a while separated, in laboring for the advancement of the next International Medical Congress. The present editors of the MEDICAL AND SURGICAL

Reporter have shared the sentiments of the majority of the profession in Philadelphia in the past history of this question, and they trust that they are now only voicing the sentiments of this same majority when they give the coming Congress their best wishes, and promise to do all they can to make it a success and a credit to the country.

COCAINE IN WHOOPING COUGH.

In a recent paper in the *Allgemeine Medicinishe Central Zeitung*, Dr. Weissenberg, of Colberg, calls attention to the benefit he has seen to follow the use of cocaine in several different diseases. The first of these is whooping cough. In using the cocaine, he began by attempting to paint the fauces of the children with a 5 or 10 per cent. solution. But, as might have been anticipated, he soon had to abandon this plan; for the mechanical irritation of the throat, and the excitement which the process set up, rendered the method rather harmful than beneficial. He then tried the internal administration of from 10 to 20 drops of a one per cent solution of cocaine in bitter almond water. The dose was given three or four times a day, upon a lump of sugar, as Weissenberg hoped in this way to keep the medicament longer in contact with the fauces. In three or four days he found marked improvement in his little patients; and, while he does not overlook the benefit they may have obtained from attention to hygienic measures, he is disposed to attribute the fact that he has never before had such good results in the treatment of whooping cough to the use of the cocaine.

It will not escape our readers that the endeavor to cure whooping cough by merely anodyne applications to the throat, and applications which must be so unequally distributed as a few drops of a one per cent. solution mixed with a lump of sugar, lacks something in the way of scientific accuracy. Nor will the fact be overlooked that the attempt to cure this disorder with anodyne applications to the fauces alone cannot be justified from the standpoint of the believer in the germ-theory of this disease. These facts suggest interesting lines of study for the theorist. But more important to the practitioner is the fact that a careful observer has found that applications, to the throat, of an anodyne, such as cocaine, in even so imperfect a way, does good to the patients. This fact justifies the further use of this method, although it has by no means always been so successful as it has been in the hands of Weissenberg. Like other methods for the treatment of whooping cough, it has disappointed some who have tried it. Still, since there is no method of which this is not true, and since cocaine administered as Weissenberg administered it is not hard to take, and as there can be no doubt that much of the severity of whooping-cough attacks is dependent upon the hyperæsthesia of the fauces which they themselves cause, this easy method seems also to be a rational one. Let our readers try it, and give their fellow readers the benefit of their experience.

A YEAR BEHIND TIME.

Our excellent contemporary, the *New York Medical Journal*, announced on May 28, that the Pennsylvania State Medical Society would meet at Williamsport, on June 1. This is a mistake, as the meeting at Williamsport was held just a year ago. The next meeting of the Medical Society of the State of Pennsylvania will be held at Bedford, on June 29. Communications in regard to papers should be sent to Dr. S. H. Gump, at that place.

Notes and Comments.

Treatment of Functional Insomnia.

We extract the following practical points from an article by Dr. Sachs, of New York, published in the *Medical News* of May 28, 1887:

Summarizing the experience I have had in the above cases of functional insomnia seen during the last year or more, I find that I have used for treatment chloral and bromide, the bromides separately, the amorphous hyoscyamine, paraldehyde, urethan, and, in a single instance, hypnone. Morphine I have never used in these cases, as I object to it in all cases in which there is not severe pain, and certainly object to it in cases such as these, when the patient would be quite prepared to contract the habit. The bromides alone have been of occasional service to me, if given in one-half to one drachm doses, in cases of extreme restlessness; but even in these I have learned to substitute amorphous hyoscyamine in doses of about one-twentieth of a grain, repeated every three hours.

I object most strenuously to the plan advocated by Dr. W. A. Hammond and others,

of keeping these patients for a long time under the influence of the bromides. These neurasthenic patients require all the will power they can possibly command, and are in much greater need of tonics than of bromides. It is easy enough to bring about a condition of semi-stupor in such patients; but that is not equivalent to bringing about healthful sleep.

Paraldehyde I used freely about nine months ago, and for several months later. I gave it in doses of one to one and a half drachms, in claret. This dose was always sufficient to bring about sleep the first few nights, but if required beyond this time, the drug proved unsatisfactory, as the hypnotic dose had to be increased; and, while I noticed no deleterious action upon the heart or other organs, the odor it imparted to the breath was excessively disagreeable. One female patient, whom I had not had occasion to see for some months, sent for me one morning after she had had a sleepless night. She had been using paraldehyde steadily in spite of my remonstrances, and I found, on entering, that the room was actually filled with the exhalation of paraldehyde.

Urethan has been satisfactory in a number of cases. It has no disagreeable after-effects, and does not irritate either stomach or bowels. It has been my experience that the dose should be between thirty and forty grains, and that greater quantities of Merck's preparation induce wakefulness rather than sleep.

The mixture of fifteen grains of bromide and twenty grains of chloral has often come to the rescue when every other hypnotic refused to act. I have seen no ill-effects follow the exhibition of this mixture, even in cases of weak heart.

A word as regards electrical treatment. In several cases in which no other remedy could secure relief, I have been able to induce sleep by galvanism applied to the head after the patient had retired for the night. I have given galvanism in the form of subaural applications—supposed sympathetic galvanization—and by passing currents directly through the head, with one pole on the nape of the neck, and the other on the forehead; changing the poles cautiously, and allowing the current to flow in an opposite direction, and never using a current of more than two milliampères. Occasionally I placed one pole over each temple. I have not been successful in the endeavor to bring on sleep by general faradization. I would not apply faradisation to the head under any circumstances. Moreover, so far as our present knowledge goes, galvanism is more effective than faradisation in bringing about vasomotor changes.

If I have accomplished nothing else, I trust I have convinced some of you that in the treatment of these cases of neurasthenic insomnia, we are in need not so much of additional hypnotics, as of more effective means of regulating and influencing cerebral circulation.

Uses of Menthol.

Menthol is most commoly used in the form of pencils; its solutions or ointments, although possibly not so convenient, are probably more lasting in their effects.

Macdonald used a ten per cent. alcoholic solution. Steward used a solution in bromethyl. The following is a formula for a useful ointment:

℞.	Mentholi,	1	part.
	Ol. olivari,	½	part.
	Lanolini,	8½	parts. M.
	F. unguentum.		

Sig.—Lanolin migraine ointment.

For many uses, as applications to the mucous membranes, the following formula, which gives a semi-fluid product, is useful; the substance resulting may be conveniently applied by a camel's hair pencil:

℞.	Mentholi,	1	part.
	Dissolve in ol. olivari,	3	parts.
	And add lanolini,	6	parts. M.
	F. unguentum.		

In the treatment of burns the following lotion may be used in place of ointments:

℞.	Mentholi,	1	part.
	Dissolve in ol. olivari,	9	parts.
	And add aq. calcis,	10	parts. M.
	F. linimentum.		

Menthol may also be used in combination in plasters, and has in this form manifold applications.

For toothache from caries a small crystal of menthol may be placed in the hollow tooth, or a mixture of equal parts menthol and chloral hydrate. As is the case when camphor and chloral are mixed, a fluid results. A pledget of cotton may be saturated with menthol chloral and placed in the hollow of the tooth.

Rabon recommends menthol as snuff in the treatment of coryza. The effect of menthol as a local anæsthetic is much weaker than its analgesic effect. The proposal of Rosenberg to combine menthol with cocaine for the production of local anæsthesia in the nose and pharynx cannot be considered of great value. In the treatment of reflex neuroses, whose origin was the nasal cavity,

Rosenberg obtained excellent results with small bougies of glycerin and gelatin which contained one-sixth grain of menthol; these were inserted into the site of the lesion.—*Therapeutic Gazette, May* 15, 1887.

On Linear Scars in the Skin.

Dr. Jonathan Hutchinson, in the *British Medical Journal* of May 7, 1887, says:

I doubt not that many observers have remarked that it is often difficult to find an explanatlon of lineal scars in the skin, I mean those which resemble the scars of pregnancy. It is well known that they are produced by anything which has caused distension and stretching, and that they are often seen after pregnancy, dropsy, obesity, synovial effusion, etc. Sometimes stretching without distension causes them. I once saw them in a very marked form on the knees and ankles of a girl who suffered from cystitis, but who had never been fat nor had any swelling of joints. The explanation was that she had been accustomed to sit for hours together in a squatting attitude on the chamber-utensil, straining to pass water. To repeat, however, my first assertion, I have often seen them when there was no explanation whatever to be obtained. A gentleman, aged 30, came to me for a chancre, and, in exposing his abdomen, I noticed that, crossing his abdomen on each side obliquely downward, were a series of cicatricial streaks exactly like those of pregnancy. They were very conspicuous. He said that he had had them all his life, and that he used to be teased about them at school. He said, also, that a twin brother had them in exactly the same condition. This gentleman was stout, and it is possible that in infancy he was very fat, but unless this suggestion may be allowed to explain them, there was really nothing to be found. He had never had dropsy, nor any kind of abdominal distension. In these unexplained cases, it is worth keeping in mind that conditions of great local development of fat may have occurred in early childhood. I do not know how early in life these linear scars have been observed.

Abortion Following the Use of Potassium Permanganate.

J. J. Mann, M. D., of Nashville, N. C., writes as follows to the *Therapeutic Gazette* of May:

GENTLEMEN: I saw in your last issue an article entitled "Abortion following the Use of Permanganate of Potassium." I have a similar case I wish you would publish in the next issue. Last July a colored woman applied to me for treatment, and stated that her menstrual periods had never been regular before marriage, and during the three years she had been married she had gone three months at a time without menstruating. At the time she applied to me it had been one year since she menstruated the last time, but during that time her general health had been very much depreciated. I at first gave her tonics, thinking, perhaps, by building up her general health it would set things aright. After keeping her on the tonics for some time, I found she derived no benefit from the treatment as regards the menstrual periods, although her general health was greatly improved. I then put her on permanganate of potassium, 2 grains three times a day (having no idea that she was pregnant). After she had been taking it a few days I was summoned to see her, and upon my arrival I found that she had aborted, and the fœtus looked to be about two months old.

Notwithstanding some good authorities say that the permanganate does not have any influence upon the gravid uterus, yet I believe it caused abortion in this case.

The Crown Prince's Throat.

The illness and death of General Grant called the attention of many persons in this country to the subject of morbid growths in the throat. And now we fear that a similar misfortune is likely to fix the minds of many in Europe upon this painful subject. Recent despatches from Berlin indicate that there is reason to fear that Crown Prince Frederick William of Germany has a malignant growth in the fauces or larynx.

It is stated that in January last the Prince was seized with an inflammation of the throat, accompanied by a slight cough and intense hoarseness. The symptoms did not yield to remedies which had before proved successful.

Dr. Mackenzie, of London, was called in consultation, and found the prince's condition not so serious as to exclude a hope that the trouble might be removed with proper treatment in the course of time. This statement was less assuring than had been expected, and has cast a gloom over official circles. Dr. Mackenzie operated with laryngeal forceps and successfully removed a foreign growth from the prince's throat, but the prince remains liable to a relapse from a return of the tumor. Virchow is said to have examined the portion of tumor re-

moved, and to have declared that it was not malignant.

A Heroic Method of Producing Emesis.

We have received from a Boston correspondent (says the *Therapeutic Gazette*) a letter from which the following extract is taken:

"I have never yet seen in any work on materia medica, therapeutics, or toxicology, the following method of emptying the stomach in cases of opium-poisoning. I have found it rapid and effective in two cases. It is entirely mechanical, but acts in a very short time: Four to six ounces of sodii bicarb. stirred well into a goblet of water and swallowed. In a few moments follow it by a goblet of good vinegar. The result is that a perfect fountain of the mixture, with the contents of the stomach also, flies out of the mouth into the basin. I first heard of it from Dr. Henry G. Clark, of this city."

To this the editors of the *Gazette* reply: "We think that this method of causing emesis has not been widely practiced in the profession. It is certainly very heroic, and to one who has never seen the play of this human geyser, somewhat appalling. Probably in a strong, vigorous patient, the plan would not be able either to produce fatal strangulation or rupture of the stomach."

Novel Surgical Operation.

A patient from the interior of the State was operated upon recently at the Jefferson College Hospital, in this city, by Dr. J. M. Barton, one of the surgeons of the hospital, for chronic obstruction of the bowels, which had existed for about one year. The operation was one which, it is stated, had never before been performed here, although similar ones had been performed by Professor Loretta, of Bologna. The patient having been placed under the influence of an anæsthetic, Dr. Barton opened the abdomen, and found that the calibre of the large and small intestine, at their junction, had become contracted to the size of a quill. The intestine was opened beyond the obstruction, and, by means of instruments and the finger, the contracted portion was dilated to its natural size. The wounds were then closed and dressed, and the patient is now in a convalescent condition and practically out of danger. In the cases reported by Professor Loretta, the dilatation was effected at the pyloric orifice of the stomach and was done for cancerous growths.

A Clean Double-Barrelled Catheter.

Dr. H. N. Allen, of Seoul, Corea, writes as follows in an exchange: "Such an instrument may be readily improvised for washing out the bladder (especially of a female), by making an eyelet on the opposite side of a No. 12 rubber catheter, and passing into the No. 12 one of say No. 4 size. The fluid can then be injected through the No. 4, coming out through the regular eyelet of No. 12, and returning through the newly-made eyelet. As this idea occurred originally to me, I presume it has already occurred to many other practitioners. But as it may not have suggested itself to every one to whom it may be useful, I mention it for what it is worth. It allows the employment of a new, clean instrument for every case, as well as supplies the demand when the regularly-made article is not at hand."

The Pulse in Morphinomania.

At a recent meeting of the Académie des Sciences, MM. B. Ball and O. Jennings described certain characteristics of the pulse in morphinomaniacs. The pulse is normal during the period of satisfaction, while the patient is still under the influence of a recent puncture. When he begins to feel renewed craving, the pulse presents a flat elevated surface; this indicates the diminution of cardiac impulse, and explains the sensation of weakness experienced by the patient. The presence of this flat surface is useful in the diagnosis of morphinomania. Treatment should be directed to the stimulation of the heart.

Incubation and Transmission of Epidemic Parotitis.

Three cases are reported by Dr. Roth, which aid in establishing the time of incubation and the manner of transmission of mumps: The period of incubation in all three cases was eighteen days. The first case was caused by actual contact; in the second, the infectious material was apparently brought by the physician himself from a patient in the hospital to another patient in his home; in the third case, the patient used the same bedding which had previously been used by a patient with parotitis.—*Boston Medical and Surgical Journal, May* 19, 1887.

Wound of the Heart.

A man named Mulcahy was shot recently in Cork, and died nine hours after removal

to the Infirmary. It appears that the bullet passed through the pericardium, the right ventricle of the heart, the left auricle, and again through the pericardium to the front of the spinal column. The interesting point of the case is that the man lived for nine hours after the infliction of such a wound.

Correspondence.

Fractures of Long Bones in Infants.

Eds. Med. and Surg. Reporter:

Sirs: The following is a description of a simple device which I have used with the most gratifying results in the treatment of fractures of long bones in infants.

Take a piece of common rubber adhesive plaster of the length of the limb, and wide enough to almost, but not quite, encircle it. Upon the back of this glue lengthwise strips of cigar box or other thin wood. Let the strips be ¼ in. wide, and let them be glued from $\frac{1}{12}$ to ⅛ in. apart. This makes an easily applied and self-retaining apparatus. All that is necessary is to bring the fractured ends of the bone in apposition, wrap the plaster carefully around the limb, and hold it there until firmly adherent. It may be left on until union takes place.

The advantages of such an appliance over plaster, and other dressings, in the treatment of this class of cases, are too apparent to need mentioning. I send you a description of it in the hope that it may be of service to some of your readers, to whom the idea may not have occurred.

Edwin B. Teft, M. D.

New Rochelle, N. Y., May 25, 1887.

On Paragraphing.

One of our most valued contributors writes from Indiana as follows:

Eds. Med. and Surg. Reporter:

Sirs: Yours of the 26th inst. received duly. I wish you all possible success, and have not the least doubt that you will succeed. I have been a subscriber for the Reporter a number of years, and have contributed to its columns, as I have to various other journals throughout the country. There are a great many subjects in our science which are by no means exhausted, and which will yet bear many *brief* and *practical* remarks.

I am trying---as you have no doubt observed, to introduce the style of "paragraph contributions" among physicians, thus doing away with the old custom of occupying a dozen pages in saying what might be said in a dozen words. Of course there are certain subjects, articles, papers, and contributions, etc., which cannot very well be condensed and treat the matter written upon exhaustively. But in the great majority of instances, a mere paragraph or two is all that is necessary if properly occupied. I do not believe any article of a single paragraph is ever allowed to pass unread. * * * * * * I believe you are the *only* editors who *advertise* or *announce* that you will *pay* for original articles. I have received pay for contributions from editors, but they did not care to have it generally known that they ever compensated in *cash* those who wrote for them. Yours, etc., **

May 31, 1887.

[We do not desire undue credit, and we are glad to state here that the *Medical News* of this city also offers remuneration to contributors to its original department. We earnestly endorse and commend to our contributors the remarks of this correspondent upon the advantages of condensation.—Editors of the Reporter.]

Is Homœopathy Increasing?

St. Louis, Mo., May 21, 1887.

Eds. Med. and Surg. Reporter:

"Homœopathy has increased and is increasing in the United States."

Will you kindly answer the above to decide an argument?

Yours truly, A. T. Genaus.

[We would be very glad to have our readers answer, each for his own locality:

1. Whether, or not, the number of persons practicing under the name of "homœopath" is increasing?

2. Whether, or not, the number of persons under the treatment of homœopathic practitioners is increasing?

3. How the state of affairs is to be explained?

We will follow with our own opinions on this subject.—Editors of the Reporter.]

—A statue to Broca, the celebrated surgeon and physician, is to be erected in Paris some time during next August. The place chosen is on the Boulevard St. Germain, near the corner of the Rue de l'Ecole de Médecine. The statue is now exhibited at the Salon. It is the work of a deaf and dumb sculptor, M. Chopin.

News and Miscellany.

Druggists' Orders.

A Cambridgeport druggist has made a practice for some years of saving in a scrap-book some of the most peculiar orders which he receives. "We are asked for some rather strange things," he said to the writer, "but we can generally guess what is wanted. Many people expect a druggist to prescribe for their ailments, as it saves physicians' charges; and the diagnoses of complaints which come to us are often amusing. Look at these: 'Send me some of the essence you put people to sleep with when you cut their fingers off.' That evidently means ether. 'I want something to take tobacco out of my mouth.' Of course, the scent of tobacco was the thing objected to. 'Send me a baby's top to a nursing bottle,' means, without doubt, a nursing-bottle top. 'An ounce of the smelling stuff that goes through your brain.' describes very well the effect of inhaling ammonia. 'Something for a sore baby's eye,' is not easy to mistake, though stated rather oddly. Here is a startling order for 'enough epicac to throw up a girl 4 years old.' We cannot help sympathizing with this person, who asks for 'enough anise seed to take the twist out of a dose of senna.' Here is a graphic description of a certain ailment in a request for a 'plaster for a man kilt with stitches.' Perhaps the one who wrote this order for 'something for a caustic woman,' built better than he knew. Here is a request for 'something to knock a cold out of an old woman.' The next one seems to be in hard condition. She desires 'something for a woman with a bad cough and cannot cough.' No druggist would hesitate for a minute to fill this order: 'Something, I forget the name, but it is for a cure.' 'Our own preparation' will just fill the bill in such a case. But what would we send for 'a swelled woman's foot,' 'a man with a dry spit on him,' and 'a woman whose appetite is loose on her.'"

Child Crying in Utero.

Dr. R. G. Loverock sends the following interesting note to the editor of the *Medical Press and Circular*, which appears in that journal for May 11, 1887:

In a medico-legal view, I think the following case well worth reporting: On the 7th of January last, I was called upon to attend Mary R., aged 22 years, a traveling photographer's wife, in her first confinement. She was lodging in this village at the time. On my arrival, I was informed by the midwife that the show had come away, and that the woman had had labor pains for a few hours before. On examination, I found the os dilated to about the size of a shilling. I left instructions as to the case, and returned to see the woman at 11 p. m. The os was then well dilated, and the case looked as if it would end as a natural labor; but at six o'clock on the morning of the 8th I was sent for, and finding the head locked in the brim of the pelvis, not having made any advance since my last visit, I ruptured the membranes, gave a dose of ergot, and applied the long forceps with some difficulty. I then waited for the first pain, and made traction, when the child (still *in utero*) was heard to cry audibly, not only by myself but by the midwife and another woman who was in the room. At each pain, when traction was used, this occurred, until the head was outside the vulva. The child was alive and healthy when delivered, and is still alive.

Selection in Breeding.

We print the following clipping from the *American Agriculturist* for June, because it is almost as suggestive to the philosophic physician as to the stock-breeder. The coupling of two animals cannot, *of itself*, produce qualities to a degree greater than the sum of that to which they exist in the animals and their ancestors. The breeding of animals can create excellence only by addition and holding the same. In the true sense of the term, qualities in animals are *created* only by environment. For breeding to make any improvement, there must first be one superior animal, and its superiority can come only of more favorable conditions surrounding it. Hence improvement is made along two lines: By surrounding animals with favorable conditions, and by selection in breeding. The first produces in individuals greater merit than is possessed by those animals not so happily situated; the second combines and holds this merit. The animal of superior merit not only has more good points than the average animal, but it has fewer bad points; and when two superior animals are selected and bred, their merits are doubled and their defects are divided, as compared with the merits and faults of animals reproduced in their offspring. It is plain that selection in breeding can accomplish nothing, unless the animals are first surrounded by unusually favorable conditions. On the other hand, favorable envir-

onment is of little value without selection in breeding, for the good results produced by it may be lost with each animal. There will be no aggregation and retention of merit. Hence the two must go hand in hand.

Ten Students Make a Peculiar Experiment With Tapeworm Eggs.

Late reports from Geneva, Switzerland, state that some weeks ago the distinguished scientist, Dr. F. Zschokke, and ten of the students at the Zoölogical Laboratory, undertook a heroic experiment for the purpose of studying the development of tapeworms in the human system, to which end they swallowed some eggs of the repulsive parasite. From every part of Europe they received letters of approbation and encouragement. The eggs had been taken from a variety of fishes known or suspected to be transmitters of the tapeworm. For nearly two weeks everything went well, but in the course of the third week the presence of the unpleasant guests manifested itself plainly with most of the experimentalists. In every instance a complete removal of the parasite was effected, the specimens extracted varying in size, two or three reaching a length of six feet. Dr. Zschokke is about to publish the result of this experiment.

New York Medical Missionary Society.

During the past week the managers of the New York Medical Missionary Society conferred in regard to enlarging the scope of their organization, and decided to insert the word "International" in the place of "New York" in the name of the Society. The chief operations of the Society will be the training of men and women to go to foreign countries as medical missionaries, the establishing of medical missions in the cities of the Union and elsewhere. Nearly two thousand young men and women have offered themselves for missionary service during the last few months.

The managers realize the value of medical knowledge in the mission field as an agency to overcome prejudice, establish confidence, and thus obtain an entrance for Christianity. The Society is composed of members of the leading evangelical denominations, and the strictest economy is practised by its students and missionaries, the latter becoming as far as possible self-supporting.

Medical College of Ohio, Cincinnati.

Prof. W. W. Dawson, for many years Professor of Surgery, has discontinued didactic teaching, but will remain in the College Faculty as Professor of Clinical Surgery, delivering weekly clinical lectures at the Good Samaritan Hospital.

Prof. Thad. A. Reamy also retires from didactic teaching, having accepted the position of Professor of Clinical Gynæcology, and will continue to address his classes in the Cincinnati and Good Samaritan Hospitals.

Prof. P. S. Conner has been appointed to the position of Professor of Surgery and Clinical Surgery.

Prof. Jos. Ransohoff becomes Professor of Anatomy.

Dr. J. L. Crilley, for many years Demonstrator of Anatomy, has been appointed Adjunct Professor of Anatomy.

Dr. F. Kebler, who has heretofore been lecturer on Pathology, has been appointed Adjunct Professor of Practice and Lecturer on Hygiene.

American Medical Missions in Siam.

On May 5, Secretary of State Bayard received a despatch from the United States Minister at Bangkok, reporting that the Siamese King and Queen, who have lately returned from a visit to Petchabure, had expressed much gratification at the course pursued by the American missionaries there, and stating that their majesties had made large gifts of money to the hospital established by them, and to the missionary schools in charge of Misses Coit, Small, and Neilson, at that point. His majesty presented Rev. Mr. Dunlap with a handsome gold watch and chain, and Dr. Thompson, a graduate of the University of Pennsylvania in 1886, with a gold medal and pencil, for their meritorious conduct in assisting the sufferers of a gunboat which exploded her boilers near Petchabure. The king also manifested in other ways his high regard for the work which the American missionaries are doing in Siam.

Death of Professor Gosselin.

Athanase-Léon Gosselin was born in Paris in 1815. He graduated there as Doctor of Medicine in 1843, and filled several important posts, such as those of head or consulting surgeon of the Lourcine, Cochin, Beaujon, Pitié, and Charité hospitals. He was also much appreciated as a professor at the Faculty of Medicine. In 1860 he was elected to the Academy of Medicine, and in 1874 to the Academy of Sciences, in the

place of Nélaton. As a token of mourning, the Monday meeting of the Acadamy of Sciences adjourned after an allocution by the Vice-President. On Tuesday similar action was taken by the Academy of Medicine, while the Faculty was closed on the occasion of the Professor's funeral.

Careless Microscopist.

Owing to the Teutonic taste for raw ham, every German town has an official microscopist whose duty it is to examine all the hams placed in the market. At Schebitz recently several persons died of trichinosis, and the court, having found a verdict against the microscopist for careless performance of his duty, condemned him to two years' imprisonment. So says an exchange. It was certainly carelessness, for no microscopist can fail to recognize *trichina spiralis* if he makes a thorough examination of the meat.—*Pacific Record of Medicine and Surgery, May* 15, 1887.

A Touching Incident.

The following account of the late Dr. Wilson Fox's last moments, when his friend, Dr. J. Russell Reynolds, was at his bedside, is given in the *Lancet's* obituary: "On the next morning, when obviously and consciously dying, and after his eyes had been fixed for a few minutes on the angle of the room, and as some gray streaks of dawn were entering it, he said suddenly: 'There is a great light, a great glare of light. . . . I feel so strange . . . a glare of light. What is it, Reynolds?' The reply was: 'It is the peace of God.' He grasped his friend's hand firmly, and said: 'God bless you.'"

American Medical Association.

PHILADELPHIA, May 31, 1887.

EDS. MED. AND SURG. REPORTER:

At this late hour I find the railroad will *not* issue certificates except through Dr. L. H. Montgomery, 189 Randolph street, Chicago, Ill. Please insert in REPORTER. It has given me much extra work to notify delegates to this effect.

Truly yours, WM. B. ATKINSON,
Permanent Secretary.
1400 *Pine street, Southwest cor. Broad.*

Sulphur.

Prof. Hugo-Schulz, of the University of Greifswald, in the *Deutsche medizinische Wochenschrift,* after many trials of sulphur in chlorosis, arrives at the following conclusions: In true chlorosis where iron is not producing the desired effect, sulphur may be given with advantage. After the employment of sulphur for some time, iron acts with greater effect. In cases of chlorosis complicated with catarrh of the stomach, sulphur is not well borne.

Items.

—Dr. Fehling has been named Professor of Obstetrics and Gynæcology at the Faculté de Médecine at Basle.

—Dr. F. P. Henry, of Philadelphia, has been elected a corresponding member of the Royal Academy of Medicine of Rome.

—"I see that bacteria have been discovered in Hudson River ice," observed Fangle. "Ah!" replied his wife; "that will be another excuse for raising the price, I suppose."

—Excessive rope-jumping has already begun to send the little ones prematurely to their graves. The death of a girl in Pittsburgh last week was ascribed to it, and so also is the precarious condition of another child in the same city.

—It is said that a Baltimore "doctor" prescribes a good many love powders to anxious patients, and a druggist of that city makes a good thing out of compounding the prescription, which is as follows: "Pura sacchara alba, hydrant aqua. Take as directed."

—The alteration of vulcanized rubber, according to Pharmacist-Major Balland, is owing to the formation of sulphuric acid, resulting from the slow oxidation of the sulphur employed for vulcanizing. To prevent the destructive change, he recommends a simple washing of the objects with plain water or water slightly alkaline, repeated every two or three months.

—This is the way the *Sacramento Bee* puts its sting into the doctors: "A Chinaman has been acquitted at Red Bluff on a charge of practising medicine without a license. There are oceans of Caucasian doctors in this State who ought to be hanged for practising with a license, and they are the very first to grumble when anybody despatches his victims to the coroner by any other route than the 'old school.'"

—Gov. Beaver has appointed Dr. Harry B. Brusstar, of Birdsboro, Berks county, Lazaretto Physician at the port of Philadelphia in place of Dr. Francis S. Wilson, who has resigned. Dr. Brusstar is 36 years of

age, and graduated in 1873 from the Jefferson Medical College, and practiced medicine in Birdsboro ever since, with the exception of two years spent in Schuylkill county.

—"Stop smoking," said a doctor to an ailing patient the other day, "and it will lengthen your days." The patient stopped. The doctor's prediction was verified. The first day, the patient declares, was as long as his whole previous life; and he was inclined to favor the idea of "a short life and a merry one."

—In Akron, Ohio, an electrical M. D. is treating consumption, seeking out the tubercular deposit, and destroying the microbes in their lair by electrical currents. The super-sensitiveness of these points is such that a current which merely creates a slight tingling at any healthy point on the surface is quite painful when brought over a mass of tubercles, and, in the words of a correspondent, "is a stroke of lightning to the tubercular microbe." There are many firm believers in the efficacy of the Akron physician's treatment.—*Exchange.*

—The San Francisco *Examiner* calls upon all adult male citizens to boycott the plug hat and to indulge in the use of hair oil. "Much," it says, "as we sometimes laugh in our sleeves at the vanity of using hair oil, yet the experience of the African Nubians, who consume all the grease they can get on their woolly heads, would seem to favor the practice in preference to water, which most generally contains more or less matter that is injurious to the hair. There is no baldness among the Nubians, whose hair is greased stiff all the time, besides living in the scorching sun."

OBITUARY NOTICE.

DR. THOMAS F. ROCHESTER.

Dr. Thomas F. Rochester, a leading physician of Buffalo, died of Bright's disease at his residence in that city on May 24.

Dr. Rochester was descended from colonial English settlers, and was born at Rochester, October 8, 1823. He graduated from the University of Pennsylvania in 1848, and was assistant physician at Bellevue Hospital, New York, for a time. He afterwards continued his studies in Europe. In 1853 he established himself in Buffalo, taking a chair in the University in that city. He was a prominent member of different medical societies, and well known as a professional author.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS.

U. S. Marine Hospital Service, for the week ended May 21, 1887:

Goldsborough, C. B., surgeon. Leave of absence extended to June 1st, on account of sickness, May 18, 1887.

Guitéras, John, passed assistant surgeon. Granted leave of absence for four days, May 21, 1887.

Armstrong, S. T., passed assistant surgeon. To remain in charge of service at Memphis, Tenn., until further orders, May 21, 1887.

Devan, S. C., passed assistant surgeon. Leave of absence extended thirty days, May 19, 1887.

Carrington, P. M., assistant surgeon. Ordered to U. S. Revenue Steamer "Rush," May 18, 1887.

Norman, Seaton, assistant surgeon. To proceed to Marine Hospital, Baltimore, Md., for temporary duty, May 20, 1887.

Heath, T. C., assistant surgeon. Granted leave of absence for thirty days, May 18, 1887.

Woodward, R. M., assistant surgeon. Appointed an assistant surgeon, May 20, 1887. Assigned to temporary duty at the Marine Hospital, Baltimore, Md., May 21, 1887.

From May 22, 1887, to May 28, 1887.

Major V. B. Hubbard, surgeon, granted leave of absence for one month, to take effect on or about June 1, 1887. S. O. 119, A. G. O., May 24, 1887.

Captain F. W. Elbrey, assistant surgeon, found incapacitated for active service by an Army Retiring Board, sick leave still further extended until further orders on account of disability. S. O. 116, A. G. O., May 20, 1887.

Captain H. G. Burton, assistant surgeon, granted two months leave of absence on surgeon's certificate of disability. S. O. 107, Div. Atlantic, May 25, 1887.

In the Medical Corps of the Navy, for the week ending May 28, 1887:

Passed assistant surgeon C. W. Deane, detached from Dale and to hospital, Mare Island.

Surgeon H. P. Harvey, orders to Iroquois revoked and wait orders.

Passed assistant surgeon S. H. Dickson, detached from navy yard, Washington, D. C., and to the Dale.

Surgeon J. R. Waggener, detached from the Iroquois and wait orders.

Assistant surgeon S. Stuart White, ordered to receiving ship St. Louis, navy yard, League Island.

Dr. James G. Field, of Gordonsville, Va., commissioned assistant surgeon in the navy, May 23, 1887.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

GREEN SPRING SANITARIUM,

AND

WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten aces. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and massage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

BELLEVUE HOSPITAL MEDICAL COLLEGE,

CITY OF NEW YORK.

SESSIONS OF 1887-88.

The REGULAR SESSION begins on Wednesday, September 21, 1887, and ends about the middle of March, 1888. During this Session, in addition to the regular didactic lectures, two or three hours are daily allotted to clinical instruction. Attendance upon at least two regular courses of lectures is required for graduation.

The SPRING SESSION consists of recitations, clinical lectures and exercises, and didactic lectures on special subjects. This Session begins about the middle of March and continues until the middle of June. During this Session, daily recitations in all the departments are held by a corps of Examiners appointed by the Faculty.

The CARNEGIE LABORATORY is open during the collegiate year, for instruction in microscopical examinations of urine, practical demonstrations in medical and surgical pathology, and lessons in normal histology and pathology, including bacteriology.

For the annual Circular and Catalogue, giving requirements for graduation and other information, address Prof. AUSTIN FLINT, Secretary, Bellevue Hospital Medical College, foot of East 26th Street, New York City.

THE VALUE OF QUININE IN PNEUMONIA.

BY GEORGE TROUP MAXWELL, M. D.,

Of Ocala, Florida.

It will be observed that in the caption to this article I have changed that of Dr. Hiram Corson's, which appeared in this journal May 21, by omitting the words "as an antipyretic."

As a constant, careful reader of The Medical and Surgical Reporter for years, I have become acquainted to some extent with the writings of Dr. Corson. I recognize in him a man of mature years, of large experience, extensive learning, and, generally, of sound discretion; but one who has extreme views on some subjects, which he holds with death-like tenacity. I always read what he writes with interest, and oft-times with profit; and in venturing to differ with him, I shall do so with great respect for him, and with some hesitation as to the correctness of my own views. I agree with Dr. Corson in his condemnation of quinine "*as an antipyretic* in pneumonia, and in other diseases." I have had long and much experience with it in many diseases, and have unlimited confidence in it in all fevers caused or complicated by the malarial poison, but if quinine has the effect of reducing the temperature to an appreciable degree, excepting in the stage of deliquescence, when in every type of malarial fever it arrests the fever perfectly and permanently, I have never discovered the fact. I say this with some degree of boldness, for during 39 years I have given quinine freely and fearlessly in every form of fever, essential and symptomatic.

About ten years ago I attended an old gentleman at Newcastle, Delaware, who is yet living and vigorous, though nearer 90 than 80 years of age, in a severe and protracted attack of pneumonia, the only case of pneumonia I can recall in the last 30 years, except those following measles, that did not yield to quinine within a week. After his recovery he said to me: "Dr. Maxwell, if I survive you I will plant a cinchona tree at the head of your grave as the most appropriate monument that can be erected to your memory." This to show my enthusiastic advocacy of quinine then and always.

But whilst joining Dr. Corson in condemning quinine *as an antipyretic*, I beg permission to enter my protest against, and to express my difference with him *toto cœlo* in his views as to the valuelessness of quinine *in pneumonia*. I understand Dr. Corson only to deny to *quinine* antipyretic effects, and not to oppose the use of antipyretics, for he characterizes "the judicious and continued use of the cold pack," by Dr. Emmett Holt, as "a bit of common sense."

After traveling with Dr. Corson thus far, and agreeing with him fully in withholding from quinine the credit of having antipyretic effects, we must now separate unconditionally. When Dr. Corson endorses the conclusion that "the bad effects of it (quinine in pneumonia) more than counterbalanced the good effects," and when he characterizes "the practice" of giving it in large doses in pneumonia as "most fatal," he is simply mistaken, and I am bound to believe that his prejudice has kept him from "trying" it. Observation of hundreds of cases, during the

last 30 years, in every climate, from Lake Erie to the southern limit of Florida, with a fatal result of less than 1 per cent. except in cases where disorganization of the lungs had progressed beyond reasonable hope of resolution, makes me *know* that Dr. Corson is mistaken, and that his condemnation of "the practice" is unjust.

I approach a case of pneumonia in the first stage—congestion—or the second—hepatization—with as much confidence of a favorable result, *within a week*, as I do one of malarial fever; for *the cause, in each disease, is the same, and the remedy is the same.* I do not mean, however, to be understood as asserting that there are not cases of pneumonia which are entirely disconnected from, and independent of, the malarial poison. That of the old gentleman at Newcastle, Delaware, before mentioned, was one; but such cases are exceptional and few.

Of course, in the view here presented of the relation of cause and effect between the malarial poison and pneumonia, I do not claim either originality or novelty. By reference to the great work of Prof. Joseph Jones, of New Orleans, "On Fevers," recently published—pages 322, *et seq.*—it will be seen that the idea has long been entertained and often expressed, and the practice of "treating it as a malignant remittent," by administering the preparations of cinchona, is followed. I do claim, however, that, if I have learned only one fact from over forty years' study and practice of medicine, it is that pneumonia, as it occurs in malarious districts, is in almost every instance as amenable to the action of quinine as are the several types of malarial fever; not, however, because of its supposed antipyretic effect; for, in the language of that "brave, learned woman," Dr. Mary Putnam-Jacobi, in admiration and respect for whose scientific attainments I will not yield to Dr. Corson, "it is an efficient remedy only so far as it affects the morbid process."

Why the malarial poison tends, in warm seasons and low latitudes, to produce congestion and inflammation of the spleen, liver, and other abdominal viscera, and in cold weather and high latitudes, to cause congestion and inflammation of the lungs and other thoracic viscera, I have not the time now to consider; but that such is the case my observation and experience have demonstrated. And the physician who, in either case, treats the organic lesions, which are secondary effects, instead of the blood-changes, which are the direct and primary effects of the malarial poison, makes a serious, I had almost said, *a grave* mistake.

I suspended work on this article for a day, that I might report the result of a case of pneumonia then under treatment.

Tuesday morning, May 24th, at 6 o'clock, I was called to see Joseph Potter, aged 20, but having the appearance of a poorly developed, delicate boy of 16, having been stunted by the malarial poison. I found him with high fever, difficult breathing, lancinating pain in left side, and cough with rust-colored expectoration. Auscultation disclosed inflammation of the lower lobe of the left lung, and its investing pleuræ. Here was a typical case of pleuro-pneumonia. I ordered:

℞. Quin. bisulph., grs. xxiv.
Morph. sulph., gr. ss.
Ft. capsule vj.
Sig.—Take one every four hours.

The left side of the chest was also to be enveloped in a warming plaster made of equal parts of strong mustard and wheat flour, mixed with cane syrup; to be covered with thin cloth. (Mustard only irritates whilst moist. Water and vinegar dry too quickly. White of egg and glycerine are good; but I use cane syrup, because in this country it can be found in almost every family.)

Wednesday, 25th. Boy better, but still very sick. Ordered quinine and morphine continued, and a small dose of Rochelle salts.

Thursday, 26th, a. m. Much better. Bowels had been moved quietly, twice. P. M. Fever almost gone; expectoration more copious, but still rust-colored. Stopped treatment.

Friday, 27th, a. m. (to-day). Boy convalescent. Discharged, with injunction to be very prudent, and to take tonics and nutritious food.

One other case: April 23, 1885, I was called to see D. M., aged 22, an athlete of superb physique. Found him with a well-pronounced attack of double pneumonia, high fever, pain and constriction of chest, livid complexion, and cough with rust-colored expectoration. Ordered bisulphate of quinine and morphine, as in the other case, and covered chest with warming plaster.

Friday, 24th. Much better. Continued treatment.

Saturday, 25th. Met the young man down town, well.

I always use the bisulphate of quinine, because it is very soluble, and is less bulky: and combine morphia with it whenever it is tolerated.

In the treatment of all types and forms

of malarial fever, I use purgatives and aperients only for their hygienic effect, not as remedies. As I keep the water-closet and sewer connections cleansed to prevent contamination of the air of dwellings and towns or cities, so I evacuate the large intestines—the fecal reservoirs—lest by absorption the body be poisoned by its effete matter. So-called "*biliousness*" is nothing but the effects of surfeit and excrementitious absorption, which temporary fasting and gentle aperients—Glauber or Rochelle salts—will relieve.

One fact to be remarked is, that they who practice blood-letting, and free purgation with mercury and other agents which, like the malarial poison, diminish red-corpuscles, fibrin, albumen, and the nutritious salts of the blood, never neglect to give quinine. Quinine in an imperceptible manner kills the malarial bacilli, and stops the fever; but the doctor gives all, or most, of the credit to his drastic drugs, because their action appeals to his senses.

When a boy, I suffered from a protracted tertian intermittent. The nights after the fever I was as quiet and orderly a bedfellow as one could desire; but the nights before I tossed, and kicked and talked, to the great annoyance of whoever might happen to be in bed with me. When I became a physician, I reasoned that the restlessness of the night before was a prodrome, or perhaps a part of the fever. Like Tom Sheppard's religion, if I did not have the fever, "I felt it a-coming." And I concluded that, if I put off giving quinine till the fever was, or was nigh to being, developed, I would miss the favorable opportunity to strike the fatal blow to the fever, and if a favorable opportunity is lost, it means the delay of 24 hours. The remission, or favorable change in remittent or other severe forms of malarial fever, occurs usually but once in 24 hours, and almost always takes place between midnight and daylight. I find that, if I get a patient's system quininized by 12 o'clock at night, a cure is almost certain. Therefore, to arrest a remittent, or to prevent the return of an intermittent fever, I wish to begin administering quinine by 12 o'clock in the day. Then by giving one of my capsules, containing 4 grs. of bisulphate of quinine and $\frac{1}{12}$ gr. of morphine, and repeating every 4 hours till six are taken, in remittent; or till four are taken in intermittents, to be repeated in the latter type at 6 and 10 next morning, the result is almost invariably successful. It is very rare that I have to repeat, if I can begin as early as 12 o'clock m. If I can't begin at 12, I shorten the intervals, or double the earlier doses, sometimes giving 8, or 12, or even 16 grains at a dose, if I begin late in the evening.

I combine morphia because I insist on *absolute rest in bed* when I give quinine, and the soporific effect of morphia helps to keep the patient tranquil and, preferably, asleep. I will not give quinine in large doses to any one who will not consent to remain *in bed the day I am trying to abate or to prevent the return of fever.* It is my *sine qua non.*

I have four rules, viz; 1. Give quinine. 2. Give quinine in full doses, and, if tolerated, combined with an opiate. 3. Give quinine at the right time; and 4. Keep the patient in bed when under the full effect of quinine, at the time of the expected increase, or return of the paroxysm.

As soon as the fever is broken, I endeavor to restore what has been lost, by administering tonics and nutritious food, and I have never used any preparation of iron that is as good as the old-fashioned tincture of iron, with its excess of muriatic acid. If there is developed a tendency to recur, I give quinine in full doses the afternoons and nights of the 6th, 13th, 20th, and 27th days, and the mornings following, and *keep the patient in bed* till dinner time the mornings that quinine is taken. By this plan of treatment I have never, during thirty-nine years, lost a patient with any type or form of malarial fever (except the pernicious or congestive), and never have had a case to continue longer than three days.

It is not generally known that the practice of giving quinine in large doses during the febrile stage of a malarial fever paroxysm originated in Florida, and was the discovery of a Floridian. In the "Medical Statistics of the United States Army," a work published by Congress in 1854, are numerous responses by surgeons of the army to a circular letter from the Surgeon General's Office, August 14, 1843, making inquiries upon the introduction into the army of the practice of giving large doses of quinine in fever, during the Seminole war. The general tenor of those responses is to give to Assistant Surgeon Charles McCormick the credit of originality and priority. The facts are these: The late Dr. Theo. Turnbull, of Jefferson county, Florida, a most estimable man and a skillful physician, gave to a patient, by mistake, 20 grains of quinine at the height of the febrile stage. He did not discover his mistake until he returned to his home, a distance of some twelve miles. In great alarm, and with all possible haste, he went to his patient, whom

he found sweating profusely, free from aches and pains—in a word, cured. He had the sagacity to adopt the practice, and his phenomenal success gave him an enviable local reputation; so that when a member of the family of the late William Wirt, once Attorney General of the United States, who owned a large plantation in Jefferson county, and, with his family, was visiting Col. R. Gamble, upon whose plantation Fort Gamble, at which Surgeon McCormick was stationed, was located, was extremely ill, he was called into consultation with Surgeon McCormick. His advice and practice prevailed. Large doses of quinine were given during the fever, and the patient's life was saved. The recovery, under the circumstances, was deemed marvelous. Surgeon McCormick adopted the practice, and introduced it into the army. For this McCormick was lauded, whilst the modest Turnbull lived and died unhonored and unsung. *Palmam qui meruit ferat.*

P. S.—The boy Potter, whose case is reported, has not done as well as I expected. On the second day after the subsidence of fever, serous effusion into the pleural cavity took place to such an alarming extent as to threaten to overwhelm the lung, and to cause death. This unusual and unlooked-for complication was caused by the boy's anæmic condition, I think. Under the continued use of quinine and the compound infusion of digitalis, with a blister, he is now, June 2d, improving.

DIABETES AND ITS RELATION TO CARBUNCLE.

BY L. K. BALDWIN, M. D.,

Medical Referee in Philadelphia of the Equitable Life Assurance Society.

It is not my intention to attempt to write a treatise on a disease so well known and so well described in the books as diabetes mellitus, but rather to cull some facts from the mass written, and add what personal experience has thus far taught, and especially in regard to diabetes as it is preceded by, coexistent with, or followed by carbuncle. The definition of the disease as given by some writers is "that it is characterized by the persistent presence and excessive quantity of sugar in the urine." It is stated that in the writings of Hippocrates there are passages indicating his knowledge of it, and that Celsus describes a disease characterized by a great increase in the urine and wasting of the body, which was doubtless that now known as diabetes mellitus. Brinton, in his article in "Reynolds' System of Medicine," says it is probable that the name diabetes was given about the middle of the first century, but no distinct knowledge was had of it until 1674, when the sweet taste and smell of the urine was discovered by Willis. Other observers followed up the line of Willis's investigations, and proved the correctness of them by separating sugar from the urine. It seems that up to 1787 the disease was supposed to be one of the kidneys, but in that year Roll, showed that vegetable food was injurious in the disease, hence other causes than that of diseased kidneys had to be looked for to account for the abnormal secretion.

Diabetes mellitus seems to be no respecter of persons or conditions, appearing in the robust and well-fed as well as in the poor and badly nourished. From my observation, those who live freely and lead a sedentary life are more liable to it than those who live under opposite conditions. Whether race has any influence on it or not may be yet an open question, although I have never known it to occur in a negro. Climate may have some influence in its production, as it is much more prevalent in some parts of Europe than in others, being especially so in Normandy and the agricultural districts of England.

The exciting causes of diabetes mellitus are numerous; but all seem to narrow down to the direct effect on the brain and nervous system. The appearance of the disease can in many instances be traced directly to some cause which has produced a decided impression, such as shock from injuries, or anything which might lead to softening or disintegration of brain tissue. There is no doubt but that excessive mental strain is an important factor in its production, as well as sexual excesses.

I treated a case a few years ago which I am sure was due to sexual excesses. It was in the person of a stout German, over sixty years old, who had a wife twenty years younger than himself, from whom I got a history sufficiently plain to warrant me in fixing upon sexual excesses as the exciting cause in that particular case. The symptoms were well marked when he came under my charge, and the amount of urine passed daily reached as much as sixteen pints. The specific gravity was always above 1030, and sugar was present in large quantities. By a rigid diet and a general tonic treatment, the quantity of sugar grew less, and the amount of urine voided was reduced to near the nor-

mal amount. The patient's virile powers were almost entirely lost, and I am unable to say whether with his partial recovery there has been any improvement in that direction or not. He is now in the enjoyment of fairly good health, paying no special attention to his diet, has still some sugar present, but no thirst or other disturbance such as characterized the onset of the disease. Another case which I can now recall, and of which I may speak more in detail, came no doubt from overtaxation of both mental and physical strength. It has been progressive from its onset, and is likely to terminate in lesions of the brain and cord, producing general paralysis.

The relation which the disease bears to carbuncle and kindred local disorders does not seem to have claimed the attention due to such an important matter. In several cases coming under my own observation, the trouble was not suspected prior to the development of such important complications, the discovery being made then only by testing the renal secretion and finding sugar present in quantities greater than found in health under any circumstances. I believe that a small amount of sugar may be normally present in the urine of some persons during digestion, when large quantities of saccharine or starchy matters are taken as food. I remember a case occurring a few years ago, which I kept under observation for a long time, testing specimens of urine passed at almost all times during the twenty-four hours, that passed during digestion always showing the presence of sugar, while that passed after its completion did not give the characteristic reaction. In this case the amount was never above the normal, and the specific gravity was from 1026 to 1030. No symptoms have yet occurred to indicate diabetes, and the subject is in good health. I have watched the case with some interest, fearing the development of carbuncle or some kindred troubles, but none have yet appeared.

The case to which I alluded in the beginning of the paper, has been one which I have watched with a great deal of interest. The subject was a man about 50 years of age, leading a very active life, a man of large means and considering himself to be in good health. About a year before I saw him he had a carbuncle on his back, but recovered from it—as is often the case—without thinking it of serious importance. I had occasion to examine a specimen of his urine, which I found to be abnormal in quantity and to contain large quantities of sugar. He became interested in his own case, and from the history he afterward gave me I am sure he did not suspect that he was in other than good health. A relative of his chided me quite severely for giving an unfavorable opinion in his case, and rather pointedly hinted that I did not know what I was talking about. By my advice he put himself under the care of his physician, and since that time he has been on a generally restricted diet, coupled with appropriate treatment, without any abatement of symptoms. The disease has gradually grown worse, and is likely to terminate fatally within a comparatively short time. One side is now paralyzed, and his mental capacity is becoming impaired. His physician told me that after the paralysis occurred the sugar disappeared entirely from his urine. The last specimen I tested, which was about five months ago, still contained sugar in considerable quantities.

Another case was in a person of supposed good health, about 35 years old, and so far as he was able to judge of himself, clear of all trace of disease. His family record was first-class, and his ancestors were long-lived. His habits of life were good in every particular. His trouble, as far as he knew, and as would appear to any one from casual observation, commenced with carbuncle. He had several of them over the spine at different times, and with them appeared the saccharine urine, and the thirst which usually accompanies diabetes. It is now at least five years since the trouble commenced, the urine, so far as I know, always having showed sugar, and his general health gradually giving way. I saw him a short time ago, and he looked badly, and complained of tiring out on very little exertion. The case is slowly going on to what will evidently be a fatal termination.

While it seems clear that carbuncle is an effect, and not a cause, of the disease, yet in some cases it also seems possible that cause and effect may appear almost simultaneously. But, attention not being called to symptoms requiring examination of the urine, it cannot easily be determined whether or not the carbuncle precedes the other symptoms of the disease.

Another case which was brought to my attention a short time ago by a professional friend, was not suspected prior to the appearance of a large carbuncle on the back of his neck, which, though large and deep, gave very little pain. I suggested an examination of the urine, and made it in the presence of the physician. I found the urine

of high specific gravity, and containing both albumen and sugar in large quantities. The case reached a fatal termination during the existence of the carbuncle. I have no doubt but that the disease had long been going on undiscovered in this case, as the patient's former habits of life had been conducive to rapid tissue changes.

On the other hand, I have often made examination of the urine of persons suffering from carbuncle, and I have been surprised to find nothing abnormal. In one case, several carbuncles appeared following each other in the line of the spinal column. The combined influence of the carbuncles reduced the patient very much, yet at no time did his urine show any saccharine reaction, nor did his health seem to be much impaired in consequence.

My experience in the cases mentioned has been sufficient to prompt me to make careful analysis of the urine in all cases of carbuncle, for by so doing it will often be found to be but a local indication of a more grave disorder.

RECENT ADVANCES IN PREVENTIVE MEDICINE.*

BY GEO. H. ROHÉ, M. D., OF BALTIMORE, MD.,

Professor of Hygiene in the College of Physicians and Surgeons.

Progress in any branch of science or art may be measured either by the number and and character of new discoveries made, or by the gradual advances in the application of knowledge previously acquired. Judged by either of these criteria, the record for State Medicine during the past year is a creditable one.

In the field of epidemiology and endemiology, the progressive extension of the fifth great pandemic of cholera first claims attention. Extinguished in the portions of Italy, France, and Spain, ravaged in 1885 and 1886, it has slowly invaded southeastern Italy, Hungary, and other Austrian possessions, and has been imported into South America, whence it threatens the United States by several routes. The danger of invasion of this country is at present greater than at any time within the past three years.

Yellow fever inoculation, as practiced by Friere in Brazil, and Carmona in Mexico, has claimed a large share of the attention of sanitarians during the year. The claims made in favor of this method of preventing this scourge are now being subjected to an official investigation authorized by the United States government.

Diligent search has been made for the specific organism supposed to be the infective agent in vaccine virus, but without definite success. The results obtained are not entirely negative, however, and one may cherish the hope that a solution of this problem will soon be reached.

The relation of a peculiar disease of cows to scarlet fever, and the discovery of a specific microbe in the blood in the latter disease, have attracted much attention. The restriction of scarlet fever will doubtless be more thoroughly effected so soon as physicians are convinced of its bacterial nature, and clearly comprehend its mode of transmission. Statistics are given showing what has already been accomplished in this field.

Sternberg, Fränkel, and Weichselbaum have studied the specific microbe of croupous pneumonia, which the former regards as identical with his *micrococcus Pasteuri;* in which opinion both the other authors mentioned coincide. Dr. Baker, of Michigan, has also shown that croupous pneumonia seems to be dependent upon a cold, dry atmosphere.

Measures for the restriction of pulmonary tuberculosis are adverted to. Tuberculous patients should not be treated in the same hospital wards with non-tuberculous individuals, and prompt disinfection of the sputa and other discharges should be practiced, in order to diminish opportunities for infection. General sanitary measures should, however, not be neglected in the warfare upon the bacillus. There is danger that a too exclusive attention to the microbian factors of disease will narrow our views of epidemiology and preventive medicine.

It seems to be established that the microorganism discovered in the intestinal lesions and discharges in typhoid fever is the cause of this disease. The fact that this microbe may preserve its vitality for a considerable time in water and ice has been shown by Bolton, Wolffhügel, Prudden, and others. This, together with the well-known history of outbreaks of this disease undoubtedly depending upon pollution of drinking water, should make prompt measures of disinfection imperative in every case. The physician fails in his duty who neglects measures for the thorough destruction of the typhoid infection existing in the intestinal discharges.

The importance of disinfection of bed-

---

*Abstract of the Address in State Medicine, delivered before the American Medical Association, at the Thirty-third Annual Meeting held at Chicago, Ill., June 7-10, 1887.

ding, clothing, and other personal and household articles in contagious diseases, demands that health authorities should have under their control establishments where disinfection can be carried out on a large scale and at public expense. Such institutions are now in use in Berlin, Düsseldorf, Göttingen, Strasburg, Breslau, Leipzig, Danzig, and other cities in Europe. The results are pronounced to be exceedingly beneficial. Steam under pressure is regarded as the best disinfecting agent.

Quarantine, a word which for more than five centuries has been synonymous with barbarism, is becoming under modern methods a safeguard to the public against infection, and an advantage instead of obstruction to commerce. The results achieved at the model quarantine station at New Orleans encourage the hope, and almost warrant the prediction, that the days of the quarantine of detention, whether by sea or land, are past, and that quarantine in future will mean simply *thorough disinfection* of fomites, and, of course, effective isolation of persons already infected.

Cremation of garbage seems to be the best method yet devised for the inoffensive destruction or final disposal of solid city wastes.

The irrigation system of sewage disposal has steadily won favor. In Berlin, Breslau, and Danzig, in Germany, Birmingham in England, and Pullman and other places in this country, it has been in successful operation. Chemical precipitation and purification of sewage has also been adopted with satisfactory results in various German cities. A board of distinguished engineers recently recommended the same system for the city of Providence, R. I.

Professor Vaughan's discovery of a very poisonous ptomaine in cheese, ice cream, and milk undergoing certain chemical changes, has been confirmed by a number of investigators in various parts of the country. Vaughan's suggestion that tyrotoxicon may be found to be the poison which produces cholera infantum, opens up a new field for investigation in which every physician must of necessity be interested.

Analyses of food and drugs made during the year in Massachusetts and New York, show the wide extent to which adulteration is practiced, and how the people are defrauded. Among the most startling instances are olive oil, of which 68 samples out of 91 were spurious. Vinegar was adulterated in 79 samples out of 116; mustard 124 times in 211; white pepper 63 times in 128; black pepper 41 times in 71; mace 29 times in 45. Of nine samples of horseradish examined, only one was found genuine. A precipitate of uncrystallizable sugar and coloring matter and chloride of tin (poisonous) is sold to candy makers for making confectionery. Citrate of quinine and iron from respectable manufacturers contained 3½ per cent. of quinine, instead of the 12 per cent. demanded by the pharmacopœia. Authority and means should be given to the health authorities to protect the public from these frauds, many of which are sources of danger to life and health.

Statistics collected by the speaker show that five-sixths of the inhabitants of cities in this country have no facilities for bathing, except such as are afforded by a pail and sponge, or an easily accessible river, lake, or other body of water. The establishment of public baths is urgently recommended both as a sanitary as well as moral measure. Tub or pool baths are objectionable, both on account of expense and lack of privacy in the latter. The spray baths in use in the German and French army barracks are recommended. These are not expensive, either in first cost or administration, and allow each bather absolute privacy and the opportunity for a thorough cleansing in clean water. Public baths should be open the year round, and not only during the summer.

A number of instances are grouped together showing how the enforcement of appropriate sanitary measures has saved life. In Michigan the saving of life from one disease (scarlet fever) has amounted during the last eleven years to 3,718, or 338 per year. In 1886, appropriate sanitary measures saved the lives of 298 persons who would have died of diphtheria if such measures had not been enforced. In England and Wales, the average annual saving of life due to sanitary measures has amounted in the five years ending 1885, to 62,000. In Baltimore, a marked reduction of deaths from infectious diseases has followed the enforcement of certain sanitary precautions. In Memphis the death-rate has been reduced in six years from 35 per thousand te 23.80 per thousand. In Chicago the reduction in mortality in the last five years has been from 25.69 per thousand to 19.46 per thousand, a net saving of 17,214 lives in that city during that period.

While all advances in sanitary administration have doubtless contributed to produce these good results, the main influence is to be attributed to three factors. These are *compulsory notification of infectious diseases; prompt and effective isolation of the sick and*

infected, and thorough disinfection of all infected articles and sources of infection. These must be the watchwords of the practical sanitarian of the future.

THE USE OF ANTIFEBRIN IN EPILEPSY.

BY H. A. HARE, M. D.,

Demonstrator of Experimental Therapeutics and Instructor in Physical Diagnosis in the University of Pennsylvania.

The favorable results which have been obtained in the treatment of epilepsy in France by Dujardin-Beaumetz, and in this country by several well-known observers, led me to test its efficacy in several cases of severe and intractable epileptic cases; and while absolute cures were not effected in any of them, a very marked decrease occurred both in the number and severity of the seizures. Briefly, the cases may be stated as follows:

Case 1. Æt. 35, male; has had epileptic attacks ever since childhood, and cannot remember when the first attack came on, probably very early in his life. His attacks have become more frequent and severe within the last two or three years, until at the time he first came under my observation some ten months ago he was having as many as six or eight attacks a week. At that time he was placed on bromide of potash in the dose of 15 grains three times a day, and though this treatment was kept up almost continously this last March, no improvement of any moment showed itself. The fits had, indeed, increased in frequency, and matters had come to such a pass that he could not work, owing to their frequent occurrence. About March 15th I began giving him 5 grains of antifebrin three times a day in powder, and at the end of the week he reported that he had used all the powders, and had had but two paroxysms. The following week he escaped with two very light attacks, with scarcely loss of consciousness, from his description. Since then he has had on the average only one a week, and once or twice has missed even that. He has now been taking the drug about eight weeks, and, although not by any means cured, is certainly much relieved.

Case 2. Æt. 18, male, was brought to me by his father, a man of a very inferior order of cerebral development, who stated that his son had suffered with fits from childhood; and the condition of the boy confirmed the father's words, for he had degenerated into that form of drivelling mental imbecility which so frequently overtakes those cases of of epilepsy which arise in early youth. He suffered from as many as three to five seizures a day, and in one instance had evidently been in that condition known as the status epilepticus for as long as twenty-four hours. I gave this case also 5 grains of antifebrin three times a day, and although I had the opportunity to see him only once again in the course of a week, the father related that his fits were not so frequent, being one or two less than they had been for a week or so before.

The third case is perhaps the most interesting of the three, since it occurred in the person of a nurse-maid, æt. 35, with whose history I had been conversant for the last twelve or thirteen years, and of whose manner of life and attacks I can speak more positively. Four years ago she began to suffer from attacks which so closely resemble *petit-mal*, according to her description, that there can be no doubt of their nature; and these seizures increased in severity and frequency till about eighteen months ago, when she suffered from her first true epileptic seizure during the night, waking the family by her scream previous to the advent of the convulsive movements.

She was unconscious, and fell into a deep sleep, in which she remained till late in the morning. After this time the attacks gradually became more frequent, and although the true epileptic seizures rarely exceeded one a month, the periods in which she suffered from *petit-mal* became much more frequent and prolonged. The convulsions also occurred in the daytime as well as night. Bromide of potash in ordinary doses did not seem to control them, nor did the administration of the iodide salts, for the purpose of retarding the growth of any brain tumor, produce any change other than indigestion, and the other signs showing that the iodide was not well borne, thus eliminating any chance of specific taint, of which, however, there had never been any suspicion. There was no family history of epilepsy, except in the person of a first cousin, and the case seemed to belong to that class known as "idiopathic epilepsy," which not rarely occurs previous to the 35th year.

When placed upon antifebrin she had had as many as two attacks a month instead of one, with almost daily minor seizures. Antifebrin was now begun in the same dose as in the other cases, and though this was over two months ago, no return of the true paroxysm has appeared and the number of lesser attacks has been reduced to as few as one or less a week.

I have reported these cases because they

illustrate a class which has either been soaked with bromides without much relief, or else are traveling down hill very fast merely from a frequent repetition of the attacks. While I am well aware that this paper would be more complete if I could record cures, I think the results here reached are sufficiently interesting to earn for the drug a trial by other members of the profession.

Hospital Notes.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

Reported by Orville Horwitz, B. S., M. D.,

Demonstrator of Anatomy in the Jefferson Medical College, and Chief of the Out-door Surgical Department of the Jefferson Medical College Hospital.

Report of a Case of Sexual Hypochondriasis,

A large number of the patients who apply to the venereal specialist for treatment are men who suffer from hypochondriasis, brought about by brooding over their imaginary ailments, who will not accept the assurance of the physician that they labor under no appreciable disease, and who, leading a miserable existence, are burdens to themselves and their friends, and their end is often either the lunatic asylum or a suicide's grave. The writer has thought that a typical case, such as was recently presented to the clinic of Professor Gross, might be interesting alike to the student and the general practitioner.

On the eleventh of March last, Loring, D. C., aged 20, a carpenter, applied at the clinic to have his testicles removed, stating that this was the only way whereby he would be enabled to cease from committing masturbation; of this he felt well assured. His condition preyed upon his mind continually, and he wished to put a stop to the disgusting habit to which he was a martyr. He declared that unless he could find some one who was willing to remove his testicles he would commit murder, or some other terrible crime.

Six months previously he attempted to castrate himself, but his courage failed, and he abandoned the attempt. Two weeks before presenting himself at the clinic, he applied acid to the penis, with the hope of making the organ too sore to handle; but this had not prevented his masturbating.

He states that his sexual desires are unnaturally great, but that owing to his want of confidence as to his ability to successfully approach a female, he entertains an aversion to the sex.

He began to masturbate at the age of seven, and has continued the practice on an average of twice a night for thirteen years. Lately he has committed the act as often as ten times in a single day.

He does not suffer from nocturnal emissions. Occasionally he experiences sharp shooting pains along the course of the urethra, extending into the cord and testicles. He is compelled to urinate from twelve to fourteen times during the day, but is not annoyed in this way at night. The stream is started with difficulty; is small, twisted, and forked, with dribbling into his clothes after the act is apparently completed. He has never passed blood.

He states that his appetite is poor; that he has a feeling of gastric oppression, with disturbed sleep, heavy pains in the front and back of head; he is easily fatigued, his hand is unsteady, and he has suffered from pain in the back for the past year.

Professor Gross, in his remarks on the case, pointed out that the patient's troubles were entirely mental; that unless he could be made to listen to reason, and unless a manly spirit could be aroused in him, or a profound mental impression made upon the individual, there would be but little hope of benefiting him.

He called attention to the fact that owing to the undue and prolonged excitement of the parts involved, there was exaggerated irritability of the medullary and vaso-motor centres, which would be ultimately followed by exhaustion or anæmia of the lumbar portion of the spinal cord; a condition known as neurasthenia.

On examination a stricture was found behind the meatus, and another in the membranous portion of the urethra. There was marked hyperæsthesia. The meatus was divided, and a steel bougie of proper size was passed, and a drachm of bromide of soda was ordered to be taken every night at bedtime. The bougie was directed to be passed twice a week, and to be gradually increased in size.

This treatment was pursued for three weeks without benefit, when both the patient and his mother implored the writer to remove the testicles. Hoping to benefit the poor creature, a pretended operation was performed.

Accordingly, anatomical plates referring to the genital organs were shown and explained to the unfortunate youth, and he was

made to understand that it would not be necessary to castrate him, but that every benefit would be attained by cutting the vas deferens. He was greatly delighted that at last his wishes were to be acceded to.

He was etherized, and in order to produce a greater mental effect he was circumcised, and afterwards an incision some three or four inches long was made over each abdominal ring, of course, merely cutting through the skin and superficial fasciæ. The wound was closed by suture and properly dressed; a large bandage being applied to fully impress the patient with the gravity of the operation. He was kept in bed for two weeks, and a few days after was discharged from the hospital.

The writer was informed that the patient returned to his unfortunate habit at the end of a month from the time that he left the establishment, so that the efforts to permanently benefit him by medical and surgical means failed entirely, although the strong impression made was of undoubted temporary advantage.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

Reported by M. Howard Fussell, M. D.

Chronic Bright's Disease; Renal Asthma. Treatment by Potassium Iodide.

Robt. K., æt. 55, married, shoemaker. This patient has been a constant attendant at the dispensary since October, 1885. At that time the following history was obtained:

Born in Ireland. In this country twenty-five years. No history of any lung or kidney disease in family save the death of one daughter from phthisis. Twenty years ago had an attack of cough and dyspnœa, lasting for nearly two years. Since has been in good health until two months ago, August, 1885, when he began to get attacks of dyspnœa on exertion and at nights. The attacks at night came on suddenly, forcing him to rise from bed and go to the window for air. They would be followed by a severe coughing spell, and sometimes relieved by coughing up a large quantity of stringy mucus. The individual attacks had the character of ordinary spasmodic asthma, but there was more or less constant dyspnœa on exertion.

On examination of the chest at first visit, it was hyper-resonant throughout; expiration prolonged; no râles of any description; apex beat of heart in nipple line, with a corresponding increase of cardiac dullness; no heart murmur, but the second sound of heart was accentuated. Some œdema of feet.

He was put on tr. digitalis 10 gtt. t. d., and potass. iodidi 10 gr. every three hours, combined with ammon. chlor. and brown mixture.

At the second visit, November 31, 1885, the urine was examined and found loaded, almost one-quarter by bulk, with albumen. Casts were also found.

The administration of above mixture seems to have caused some amelioration of symptoms. He sleeps better, and has had fewer attacks of dyspnœa. He commenced taking the large doses of potass. iodidi without any symptoms of iodism appearing.

In December was put on potass. iodidi, dissolved in infusion of digitalis.

January 30, 1886, his dyspnœa almost entirely relieved; no œdema. Albumen and casts still persist in urine.

In March, 1886, at the suggestion of Prof. Osler, he was put on 1 gtt. doses of 1 per cent. sol. of nitro-glycerine; this was increased until he took gtt. iv. t. d. He has continued the use of the nitro-glycerine with more or less constancy until the present time. Each time he returned to the dispensary, however, he would ask to have his original prescription of iodide renewed, saying it gave him more relief than any other medicine. His treatment besides the above has been liq. potass. arsenit, alterating with tr. nuc. vom.

For the past few weeks, June 1, 1887, he has not been so well, the asthmatic attacks have become worse, until at present he cannot lie in bed. He has no dyspeptic symptoms, but little headache, and no vomiting. There is beginning œdema of base of lungs. Latterly his bowels have become much constipated, the only purgative which has any marked effect being Husband's magnesia; before he took that preparation he had been given large doses pulv. jalap. night and morning, without causing any purgation.

The case is evidently one of chronic renal disease, with accompany renal asthma, and some emphysema of lungs.

The treatment by large doses of potass. iodide and digitalis has been the most satisfactory, though that now is failing, and the case is doubtless drawing to a close.

In the matter of purgatives the case is a unique one in my experience; almost all the purgatives were tried without effect until the patient, of his own motion, took the magnesia, which he says will cause a profuse diarrhœa with amelioration of his symptoms.

New Instruments.

A NEW LEG-HOLDER, SECURING A PERFECT LITHOTOMY POSTURE WITHOUT ASSISTANTS.

BY HOWARD A. KELLY,
of Philadelphia.

My intention to devise some simple apparatus to secure my gynecological cases in a lithotomy position was formed some four years ago. I had been called to Port Richmond to operate upon a lacerated perineum, and Dr. Jas. S. Carpenter, of Pottsville, went with me as my sole assistant.

Dr. Carpenter put the patient under ether, and we brought her hips down over the foot of the bed, and then, to dispose of the legs and expose the field of operation, we flexed the thighs upon the belly and passed an umbrella under the knees to give purchase to our rope, which we made out of a sheet caught diagonally across corners and twisted. The broad band of the centre of the sheet passed around the neck, while the ends were tied around the two ends of the umbrella, holding the knees well up. I then operated alone, securing a perfect result. The Clover crutch in common use has served me well at many operations since that time, but it has the serious objections of being heavy and very clumsy to carry about, and above all is expensive.

Of the instruments in use in Germany, that of Sänger, in which the collars on the knees are held fast by an attachment to the part of the table under the patient's head, is one of the best.

Fritsch's apparatus, and other similar forms, are convenient in clinics and hospitals; but made as they are of iron rods and clamps, they can hardly claim the merit of being portable.

I believe that the form which I describe here, and which is in use in my private hospital, answers all the requirements as to fixation as well as any holder in use, and in other important particulars is superior to any in use.

It is simply two broad, well-padded collars of muslin, large enough to slip easily up any leg above the knee, and a broad strap made of the same, well padded with haircloth. At each end of the strap is a snap hook, and at eight and ten inches from the centre of this strap, on the inner side, are fastened galvanized rings an inch in diameter.

The method of application is this: Slip the collars first above the knees, and pull both knees as high up on the belly as possible.

Then take up the strap and snap one hook into a ring which is on the collar, carry the strap up *under* the arm and shoulder of that side, and around the back of the neck down *over* the shoulder of the opposite side, and snap the hook on the other end of the strap into the collar of that side. If this leaves the legs lax and hanging low, the hooks can be unsnapped and pulled through the collars, and snapped on the rings spoken of on the strap. The cost of the apparatus is $1.50.

I will remark finally that the strap, passing as it does to the sides, sufficiently separates the knees, and I have found no need for complicating this simple device, which can be carried in the coat pocket by the cross-bar of the Clover crutch.

2134 *Hancock street.*

Medical Societies.

THE BALTIMORE ACADEMY OF MEDICINE.

At the May meeting of the Academy two very interesting discussions occurred, one on tube-casts of albuminuria, and the other on the choice of anæsthetics.

The first was occasioned by the account of a case of obscure brain disease reported by Dr. F. T. Miles. When he saw the case the mental hebetude was great. He asked for a specimen of the urine, and tested it for albumen by the layer test, pouring in the nitric acid first, and also by heat and nitric acid, and found it absolutely clear and free from albumen, as the specimen he exhibited showed. This urine had been examined by his other physicians, and they had also re-

ported absence of albumen. Dr. Miles then took from the bottom of a vessel with a pipette a few drops of the sediment, and examined it under the microscope and found a large number of the tube casts, very faint, hyaline, and small, and no renal epithelium. If it had been a case for life insurance, he would not have thought of looking for casts when no albumen was or had been present. He wished to impress upon the society the importance of examining the urine microscopically in doubtful cases when albumen was absent. This was not the first, second, or third time that such a case had come under his notice. He had often found casts where albumen was not present, but had been present at a previous examination.

Dr. James Carey Thomas asked if Dr. Miles made such examinations for life insurance.

Dr. Miles said the retina showed us signs of nephritis, but that the renal changes might have been caused by a reflected effect upon the kidney without retinal change.

Dr. T. Ashby asked how the absence of albumen without tube casts could be explained in this case.

Dr. F. T. Miles said that the watery parts and the salts of the urine were secreted by the epithelium which covers the glomeruli, and that the other ingredients of the urine were supplied by the tubular parts. Injury of the glomeruli would allow albumen to escape in the urine and yet no epithelium would pass. He did not think the presence of albumen in the urine a matter of grave importance, but on the contrary thought that any one of the members present could find albumen in his urine at some time in the day. He said that lead, mercury or a slight congestion of the kidney were often sufficient to produce it. He mentioned Heidenhain's theory of balance. Heidenhain clamped the renal artery in a dog for a moment only, and then let it go to allow the blood to rush back into the kidney. This happened, but the urine was secreted at first only in very small quantities and was albuminous. He thought this argued against the filtration theory of urinary secretion. He referred to a case of cyclic albuminuria in a medical student. He did not look for tube casts. He said that in one-half of all cases of albuminuria there was not disease of the kidney, and in all cases of the so-called albuminuria of adolescence.

Dr. T. A. Ashby had seen several similar cases of albuminuria. He mentioned three. The first was a case of cyclic albuminuria where at times 30 to 50 per cent. of albumen was found and no tube casts. The man had repeatedly been turned away by an insurance company and was finally accepted for a small amount, and was at last accounts living and well. The second case was somewhat similar. Much albumen was found and he had at the time much headache and was declined by an insurance company, although apparently in health. A second examination later showed the same results, but no other unfavorable symptoms. No microscopic examination was made. A third case showed 50 per cent. of albumen with no tube casts present, and yet he had many symptoms of renal disease. At present he is much better, but his urine still showed albumen. He gave Basham's mixture and Buffalo Lithia water. He thought that Dr. Miles' point was a good one, and that the time would come when many life insurance companies would accept cases with albuminuria. Dr. Pavy had reported a number of cases of cyclic albuminuria.

Dr. James Carey Thomas spoke of the albuminuria of adolescence, which he considered very interesting. Such cases he thought did not go to the further development of renal disease. It was not always easy to distinguish it from renal diseases, for tube casts did not seem to be always pathognomonic.

Dr. Miles said that this albuminuria might come from some poison in the blood. (He remarked that a specimen of urine containing tube casts might be kept a long time by adding a small amount of carbolic acid to it.) He showed a specimen of urine from a patient who had had capillary bronchitis, which went on to catarrhal pneumonia, coma and death. He passed much urine up to forty-eight hours before death, and in it was found a large amount of epithelium and epithelial casts, which Dr. Miles stained with fuchsin. He could not say here what was the primary cause of death. His urine had been examined shortly before his death and he had had his life insured. He thought the kidney might take on disease at the end of life from other causes.

Dr. John Uhler said this was an important subject and required great care. He invariably took three specimens from each patient. He let the patient pass the urine in three different chambers. The first chamber contained what was passed from the urethra, the second that from the bladder, and the third from the parts higher up. He then examined the urine in the middle chamber, and thought that with care he avoided many doubtful cases. He thought we should depend on the concomitant symptoms as well as on the presence of albumen and tube

casts. He wondered that there were no retinal changes found in the case mentioned by Dr. Miles.

Dr. J. J. Chisolm said the evidences of retinitis were very marked, and could easily be detected at once, but that they did not occur with every case, that diagnosis from the retina alone was often made, but that many died without retinal changes.

In the discussion upon the choice of anæsthetics, Dr. J. J. Chisolm stated that he had had little experience with ether. Bromide of ethyl had with him supplanted the use of chloroform to a large extent. It enabled him to operate in the primary anæsthesia, *i. e.*, before the patient wakes up from the first sleep. He had had thirty-five years in surgery, and had given chloroform every day, with no death, *i. e.*, about 15,000 cases and no death. He thought it was hardly right to take the percentage of deaths, as in one case a physician whom he knew had administered chloroform once, and the case died, so that he had a mortality of 100 per cent. Bromide of ethyl would bring a patient under in one-half a minute, and in many cases if continued a half minute longer than absolutely necessary it could kill the patient. When used too long, ashiness of the face occurred, and the heart's action stopped. He had never had a death from it. It was not given in New York and Philadelphia. His inhaler was a closed tin cone, absolutely tight, lined with flannel, and rim-covered with padding to fit the face. ʒss. to ʒj. of the bromide of ethyl was sufficient. It was very volatile, so that the cone should be inverted at once. He made the patient blow out forcibly before the cone was applied. The patient was under it in a half to one minute, and had a natural appearance, unless the anæsthesia continued over one to two minutes, when the ashy skin would denote danger. The oculist probably had better results with chloroform, because the eye was so near the nose that the inhaler was removed during a part of the operation, and if respiration became difficult the chin was elevated, which had the same effect as drawing out the tongue. Had never had heart arrest. He always elevated the feet on the principle of Nélaton, who found that when a rat, thoroughly anæsthetized, was held up by the tail, it would begin to revive, and when put down would remain quiet. He mentioned a case in which Dr. Woods gave chloroform to an old man 82 years old, for cancer of the ear: respiration being arrested, they hung him up by the heel and completed the operation.

Dr. P. C. Williams asked Dr. Chisolm why he preferred bromide of ethyl.

Dr. J. J. Chisolm said for short operations the patient could be brought under anæsthesia at once, had no nausea afterwards, and could get up and go home. He thought too much could be given, just as one might give too much morphia.

Dr. Bombaugh asked if he used nitrous oxide gas.

Dr. Chisolm said it was too bulky, and difficult to prepare, and patients resisted it, and patient might wake up too soon. He thought the careful administration of chloroform free from danger. He knew little about ether. Had probably used two quarts in his life, and was ashamed to say how many hundred gallons of chloroform. Ether was too uncomfortable.

Dr. T. A. Ashby said that for several years, during his services as resident physician to the Maryland University Hospital, it was his almost daily duty to administer anæsthetics. In this way he had enjoyed a very large experience. He had never witnessed trouble from the use of chloroform, and preferred this agent to ether. During the past few years he had yielded somewhat to the prejudice against chloroform. He was now in the habit of giving chloroform in short operations. When the patient was kept under an anæsthetic for any great length of time—an hour or longer—he continued the anæsthesia with ether. He prefers chloroform in all cases where the patient bears it well. He once kept a patient under the complete influence of chloroform for four hours and a half in an operation for vesico-vaginal fistula. The case bore it well. He substitutes ether for chloroform in long operations, when the latter depresses the heart's action. He thinks the anæsthetic should be selected for the case, just as we select the operation. He thinks the merits of these two agents should not be judged in a partisan way. They both have their special advantages, and should be employed with the same intelligence and care that we employ other narcotic and dangerous drugs.

Dr. Canfield said he had seen stated in a foreign work that ether was universally used in America, the use of chloroform being prohibited by law. He knew of no such law.

Dr. Chisolm said if a death from chloroform should occur in Boston, it would be unpleasant for the surgeon. He mentioned a case related in Pancoast's surgery in which apparently not enough chloroform had been given. He thought the verdict should

have been "death from want of chloroform" rather than "death from chloroform."

Dr. Woods thought the last point was a good one. Thought partial anæsthesia very dangerous and quoted Bartholow and Lister in Holmes' surgery to prove his point.

Dr. Chisolm thought chloroform required skill; the blunderer could use ether. Ether he thought was like a dull knife for the boy, and chloroform the sharp razor for the man.

Periscope.

Cerebral Pneumonia in Inebriety.

A large per cent. of all inebriates die from pneumonia. Cerebral symptoms and complications are common in these cases, and are described by the term cerebral pneumonia. The symptoms in such cases vary widely, depending on the causes; as do also brain susceptibility and exhaustion. The effect of high fever and increased heart action on degenerate brain and nerve centers in inebriates is manifest in symptoms that often mask the pneumonia, requiring a careful examination to determine meningeal inflammation or meningeal irritation or pneumonia.

Thus, in one case, an inebriate suffered from chill and pain in the lungs. The next day he was delirious, and he died a few days later of supposed acute meningitis. The autopsy revealed the pneumonia. In another case, after a short period of exhaustion and dull pain, profound depression and melancholy came on. Except a rapid pulse and high temperature, no other symptom of note was present. He died a week after the attack, and the autopsy indicated pneumonia. In a third case, after a chill and fever of two days, the patient suddenly became delirious and remained so until death, within a week. Pneumonia was found, though unsuspected during his illness.

Magnus Huss long ago pointed out two varieties of pneumonia appearing in inebriates which are even now overlooked. The first form appeared in those who used alcohol to great excess, and all the symptoms came on suddenly. Gastric derangements and a feeling of faintness, with enervation and loss of sleep, are the first symptoms. Often a chill is the first mark of any disturbance. From this point two different conditions may come on—one of great muscular and mental activity. The face will seem to swell and the eyes to glisten and flash, the hands and arms tremble, and the patient talks incessantly, often stammering. Delusions which are first transient, then permanent, appear. Often this state closely resembles delirium tremens, but it quickly merges into extreme exhaustion and death. In some cases, the trembling delirium begins as soon as the chill subsides; in others it comes on slowly, but seldom lasts over three or four days. No complaint of pain is made, and no cough is apparent. The second condition of this disease will first appear in a sudden change of expression, sunken eyes, and great apathy of mind, high fever, rapid pulse, and a rapidly increasing exhaustion. Both body and mind seem struck with paralysis, and except a chill and hectic flush in the evening, no prominent symptoms are noticed.

In the second variety of cerebral pneumonia, an adynamic condition develops at once. Insomnia, or drowsiness, and mild delusions, appear at first. Trembling of the hands and legs and stammering speech follow; then picking at imaginary objects, whispering to imaginary persons, and finally death. No chill or cough is noticed, only high temperature and pulse.

Another form has been described, in which delirium of anxiety to do something is the first symptom. The person will go to bed with exhaustion, and have this confused and changing delirium, which ends in death in a few days. He looks badly, will not eat, has high pulse and temperature, and rolls and tosses in bed. The delirium may concern his business or family interests, and may last for two or three days, during which he will walk about; then suddenly he will go to bed, and soon after die.

These are only general symptoms, which appear among those who are greatly enervated. Almost endless varieties of symptoms will appear in those who have had syphilis, head injuries from heat and traumatism, nerve and spinal injuries, and lesions of the heart, liver and stomach.

One practical fact should never be forgotten. Whenever inebriates exhibit cerebral

changes or great exhaustion, the lungs should always be examined. A rapid pulse and high temperature should suggest the same examination. Delirium tremens or great depression, melancholy, change of face, insomnia, stupor, and other symptoms, point to inflammation of the lungs, as both a primary and secondary cause. Complications with malaria, cirrhosis of the liver, abscess in both the liver and lungs, or gangrene, are all factors to be considered in cerebral pneumonia. If the case appears as one of delirium tremens, the question of alcohol in the treatment will be prominent. How far it can be given, and how far it will aggravate or relieve conditions of disease present, are most important problems.—*Quarterly Journal of Inebriety.*

Expectant Treatment of Extra-uterine Pregnancy.

Dr. Beugnies-Corbeau, of Givet (Ardennes), describes in the *Union Médicale* of April 2, a case of extra-uterine gestation which had been left to nature, owing to the mismanagement of a former medical attendant. He saw the patient in 1883. She was robust, and about fifty years old, and was subject to epistaxis. Twelve years previously she was pregnant for the first and last time. During her pregnancy she was subject to violent attacks of abdominal pain. Her physician believed that she was not pregnant, but that she had ovarian disease. At term she was seized with labor pains. The physician came with all his instruments, and, after waiting for three days in the house without diagnosing the case, went away believing, it seems, that he had to deal with an inflamed ovarian cyst, or some kindred disease, which he was pleased to call "dropsy of the ovaries." After three years of ill health, an enormous abscess developed on the gluteal region, fragments of a fœtal skeleton came away through it, and a sinus was left, which was very slow to heal. A second abscess opened in the same region on the opposite side, a third in the hypogastrium, and a fourth in the perineum. Both hip-joints became fixed, apparently through muscular spasm. The last fistulous track discharged one of the scapulæ, which took five months in passing through the perineal structures. Being exceedingly tortuous, this fistulous passage remained open for two years. After so many years of suffering, the patient was restored to perfect health. This case does not speak volumes in favor of the expectant treatment of extra-uterine pregnancy.—*British Med. Journal, May* 21, 1887.

Herniotomy in an Infant.

Mr. J. Lionel Stretton reports in the *Lancet,* May 21, 1887, the case of an infant, 19 days old, with a right scrotal hernia, which was reduced by his assistant. Nine days later the rupture re-appeared, and all attempts at reduction failed. Fæcal vomiting set in, and the child was evidently losing ground. There had been no evacuation, and, so far as the mother could tell, no passage of flatus since the rupture appeared, thirty hours previously. Chloroform was administered, and an attempt made to reduce the rupture; this failing, an incision was made over the swelling about three-quarters of an inch in length, and the bowel exposed —an exceedingly difficult proceeding in such a small space. The stricture appeared to be situated at the inner ring, was exceedingly tight, and required two or three nicks before the bowel, which was in a healthy-looking state, could be reduced. Silk sutures were employed, and the wound dressed with oiled lint. Half a minim of tincture of opium was given every four hours. The child recovered nicely from the operation.

This case is remarkable on account of the age of the child, the immediate subsidence of all symptoms after operation, and the rapid recovery. The patient was the child of poor parents, and was brought to Mr. Stretton's house for examination. Mr. Stretton operated at once, and the infant was carried home in a blanket. He did not receive any skilled nursing afterwards, nor was it possible to prevent the dressings being soaked in urine.

Quinine in Albuminuria.

In the *Bulletin Médical des Vosges,* M. Pernet reports a case of albuminuria that was rapidly cured by the administration of quinine. The patient, a coffee-house keeper, aged 37, habitually enjoyed good health. On going to bed after a long walk in the country, during which he had perspired freely, he was seized with chills, which were soon followed by fever. Subsequently, bilious vomiting set in, with sleeplessness and loss of appetite. There was great emaciation, the skin remained dry. Pressure over the gall-bladder produced great pain. The pulse was 72. Examination of the urine revealed a considerable quantity of albumen,

but no sugar. As the patient also suffered from worms, one gramme of calomel was given, together with a small quantity of opium. On the following day the urine was found free from albumen. It was then discovered that the albuminuria was intermittent and of the tertian type. Seventy-five centigrammes of quinine were administered to the patient daily, with the remarkable result that the albuminuria disappeared as if by enchantment. The treatment, however, was continued in progressively decreasing doses for several days, when the patient entered on a period of convalescence.

Horny Growths of the Penis.

At the recent meeting of the American Association of Genito-urinary Surgeons, Dr. J. H. Brinton, of Philadelphia, read a paper in which he referred first to the cases of horny growths on the penis recorded in literature. There were only fourteen cases, the histories of which were sufficiently well given to be of value for purposes of comparison. The longest growth on record was three inches long. The specimen now presented by the author had been removed by him after it had been growing more than four years. It had sprung from the seat of a wart. It had given no trouble excepting mechanical interference with coitus. It sprang from the base of the glans, at the border of the corona, it was attached to both the glans and prepuce, was an inch and seven-eighths long, an inch and three-eighths in circumference at its base, and curved forward. An interesting feature was the fact that the meatus was involved in the growth, and so much encroached upon that the urine escaped in almost imperceptible drops. After removal of the growth with the knife, the patient made a good recovery.

Supra-pubic Cystotomy.

At the same meeting, the President, Dr. E. L. Keyes, of New York, read a paper in which he advocated the operation of supra-pubic cystotomy for vesical tumors; for certain foreign bodies; in cases of very large stone; and in some very exceptional instances for purposes of exploration. He condemned the general adoption of the method as a usual one for the removal of stone, and especially objected to its use in children. He had done the operation for a large fibro-papilloma, for a flat villous growth, and for a large calculus. He detailed his practice in dealing with hemorrhage; said that he believed in vesical suture; and described his method. He showed a new retractor, and described his method of effecting perineal drainage by puncture, probe, and catheter, without making the large incision usually considered necessary for this purpose.

Give the Babies Water.

Dr. Touissaint, in an article in the *Union Médicale de Canada*, calls attention to the fact that milk does not satisfy the thirst of babies. It appeases hunger, but it frequently intensifies thirst, and the author maintains that it is this very thirst that causes healthy children, raised altogether at the breast, to cry so frequently and so violently. We have seen peevish, fretful infants, upon whom all the arts of the nurse and mother had in vain been tried without eliciting a smile, suddenly brighten up at the sight of water, reach eagerly for it, and on obtaining a drink, go off to sleep calmly and contentedly. We quite agree with Dr. Touissaint when he declares that many cases of infantile indigestion would be benefited or cured by giving the little patients a regular supply of water. —*St. Louis Med. and Surg. Journal.*

Whooping Cough in a Cat.

In the British *Med. Jour.*, May 7, 1887, Mr. O. Bowen, of Liverpool, says: "For the past few weeks I have had under my care a little boy suffering from a more than usually severe attack of whooping-cough, and his mother informs me that for quite a fortnight their cat has had five or six distinct fits of coughing daily, similar in every respect to the boy's, which end after the expectoration of frothy mucus. The cat between the attacks is tolerably bright and active, though not so lively as she formerly was, and has considerably fallen away in condition. This is the first instance of a domestic animal becoming affected through, apparently, infection from a human being, which I can remember having observed, and it occured to me that the fact may be of interest to others.

Hemoptysis—Error of Diagnosis.

At the meeting of the New York Surgical Society, May 11, 1887, Dr. Charles McBurney mentioned the case of a gentleman who had suffered for twelve years with "hemoptysis," and had been all over Europe, frequently having his chest examined, under the impression that he had phthisis. No evidences of pulmonary trouble could be dis-

covered, and, as none of his physicians had ever chanced to see him when he was bleeding, the cause of the hemorrhage could not be discovered. Dr. McBurney happened to examine him while he was spitting blood, and found that it came from the bottom of a tooth-cavity. He was cured by removal of the tooth.

The Influence of Disease upon Population.

In a very interesting paper by Walter A. Dunn, M. D., published in the *Cincinnati Lancet and Clinic*, the author says:

The United States has doubled its population every twenty-five years for over two hundred and twenty-five years. If this rate continues for another century, the population will exceed in density that of the Chinese empire. From 7,860,000 in 1820 it has risen to about 60,000,000 in 1886. It requires only a little application of these figures to show that all known checks to the natural increase of population must be actively at work in a few years in order to keep down the results of procreation. The advance in pathology warrants the belief that disease as a factor in the reduction of population will be less potent in the future than heretofore, and other well-recognized checks are likely to be more potent.

Want is a check which constantly appears in our paths, from improvidence, intemperance, misfortune, or other reason, and as constantly lifts its head in appeal to our kinder instincts. No one can deny its marked increase in densely crowded cities. Our country produces food sufficient for at least 20,000,000 people more than its present population, and yet *want* is a check to her population, a check which is constantly growing, any which must be of more consequence as our food supply nears the point of just supplying the necessities of our own people.

The procreative instinct is one of the most powerful which exist in all forms of life, both animal and vegetable. This strong law of nature is one from which man vainly tries to escape. By moral restraint, prevention of conception and abortion, the reproduction of the species is limited by man, and he seeks by these ways to escape the strife of over-population. The struggle to exist must make them prominent in that dense population to which we are rapidly drifting. There are strong reasons for believing that long before we reach a population as dense as that predicted for this country fifty years hence, an armed struggle, within or without, will offer to surgeons unusual opportunities. Intemperance as a check to population can hardly be estimated now. The trial of prohibition is spreading among the people of the United States. Viewed in the light of the past, all must see that the advance made in pathology during the last few years is not an unmixed good, but that it throws its savings into other channels, and is compensated for in other ways.

Antiseptic Gauze.

Dr. A. G. Gerster, in the New York *Medical Journal*, describes a way to make antiseptic gauze easily and cheaply. Twenty-five yards of cheese-cloth, which can be procured at any dry-goods store for a trifling sum of money, are divided into four equal parts. Each of these is folded eight times, rolled up loosely, and tied with a string. To make the gauze absorbent it is put into a common wash-boiler, covered with water to which a pound of washing soda or saleratus has been added, and boiled for an hour. After this it is rinsed in cold water for ten minutes to free it from the soda, passed through a clothes-wringer, and placed in a stone or glass jar or an enamelled kettle, filled with a corrosive sublimate lotion of 1 to 1000 strength, to remain therein for twenty-four hours. It is then passed through the wringer again, and hung up to dry over night when the air is free from dust. The string put about each piece should not be removed until the time of drying, as it will keep the folds from getting disarranged. The dried pieces are ready for use, and will keep clean if wrapped in a towel or put away in a jar.

When the gauze is used, suitable sized pieces, each eight folds thick, can be cut out with a pair of stout, sharp scissors.

Iodoform gauze is made by sprinkling iodoform powder from a pepper-shaker uniformly over the moist compress, and rubbing it thoroughly into the meshes between the fingers.

An excellent substitute for gauze in an emergency is common cotton batting well soaked in solution of corrosive sublimate (1 to 1000). The package of batting is unrolleed in an ordinary manner, and cut into square pieces of desired size. Each of these is refolded into a small square, and thoroughly kneaded in a wash-basin filled with the mercuric solution till completely saturated. When wrung out, and unfolded to its original shape, it is ready for use. Any clean fabric of cotton or linen, soaked in mercuric solution, makes a good antiseptic dressing.

The Pathology of Albuminuria of Pregnancy.

The *N. Y. Medical Record*, May 21, 1887, calls attention to the fact that Prof. Leyden, in a recent paper upon dropsy and albuminuria in pregnancy, argues that disease of the kidneys at this time is caused solely by the conditions of pregnancy, that it begins in the second half of a first pregnancy chiefly, progresses steadily until parturition occurs, and then usually disappears. The anatomical appearances of the kidney in pregnancy have been found to vary greatly from that of acute parenchymatous nephritis to that of congestion or anæmia. Leyden holds that the condition is one resulting from long-continued arterial anæmia.

Dr. A. F. A. King, in the *American Journal of Obstetrics*, March and April, 1887, has advanced another Explanation of the Renal Troubles of Pregnancy. His idea is that the kidney troubles occurring in pregnancy are brought about by the uterus not keeping above the pelvic brim—as it ought to do—until the time of labor is reached. The normal position of the pregnant uterus and fœtus is one of lateral obliquity, the head generally lying in one iliac fossa. If, for any reason, the womb stands vertically, then the head or breech presses down upon the renal and iliac vessels.

Dr. King has studied this matter statistically, and his study seems to indicate that his views are correct. The practical bearing of this theory lies in the fact that disturbance of the normal lateral obliquity of the pregnant womb is caused by tight and ill-fitting dresses, corsets, coitus, and certain abnormal postures, all of which things can be measurably prevented.

Perforation of the Bladder.

Drs. Benham and Greig Smith record in the *Glasgow Medical Journal* the case of an imbecile who pushed the whalebone of an umbrella up his urethra and into his bladder. Two years afterwards, during an autopsy, the man having died of Bright's disease, the whalebone was found to have perforated the bladder and passed into the peritoneal cavity, one end still, however remaining in the bladder—on this extremity was a phosphatic calculus. During life, the patient never complained of any vesical or abdominal trouble.

Treatment of the Cord after Child-birth.

Prof. Budin, of the Charité Hospital of Paris, allows the new-born infant to remain undisturbed *until the cord has ceased to beat*, before tying it. It is believed that some eighty grammes of blood are saved to the baby in this way. He applies but one ligature, close to the body of the child, and cuts the cord outside of it, leaving the placental end open, except in case of twins. It has been said that this system of waiting causes jaundice in the infants. Experiments were made to test the correctness of this statement. The results proved that the waiting plan is the best.

Reviews and Book Notices.

BOOK NOTICES.

Statistique des Vaccinations Pratiquees avec la Culture Atténuée du Microbe de la Fièvre Jaune, de Septembre, 1885, à Septembre, 1886. Par le Dr. Domingos Freire, Professor de Chimie Organique et Biologique à la Faculté de Médecine de Rio de Janeiro. Paris, 1887.

In this pamphlet of 16 pages, Prof. Friere gives a résumé of one year's work in the active prophylaxis of yellow fever. His results, which are very favorable, are based upon 6,524 vaccinations.

A Contribution to the Pathology of the Cerebellum. By E. C. Seguin, M. D. Read before the New York Neurological Society, February 2, 1887. Reprinted from the *Journal of Nervous and Mental Disease*, vol. xiv., April, 1887.

Infants, their Chronological Progress.

We have received from Prof. Stanford E. Chaillé, M. D., of Tulane University of Louisiana, a fascinating little monograph bearing the above title. It is reprinted from the June number, 1887, of the *New Orleans Medical and Surgical Journal.*

Pelvic Inflammations; or Cellulitis versus Peritonitis. By Thomas Addis Emmet, M. D., Surgeon to the Woman's Hospital, New York. Reprint from volume xi. *Gynecological Transactions*, 1886.

Hygiene as a Basis of Morals. By Frances Emily White, M. D.

This interesting and suggestive pamphlet constituted an address to graduates at the commencement of the Woman's Medical College of Pennsylvania, March 17, 1887. It is reprinted from the *Popular Science Monthly*, May, 1887, by request of the class.

Congenital Occlusion of the Posterior Nares. By Alvin A. Hubbell, M. D., Buffalo, N. Y.

THE
Medical and Surgical Reporter.
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

P. O. Box 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER will be published in each number. The regular edition for this week is 5,000 copies.

THE MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

The thirty-eighth annual meeting of the American Medical Association, just held in Chicago, was one of the best and most successful meetings which have ever been held. Every portion of our broad land was represented, and able and interesting papers and discussions were presented at each session. The scientific prceedings were of great importance, and the social features of the meeting were in the highest degree successful.

One of the most interesting features of the meeting was the unmistakable desire that all parts of the country should be united together in the good work of promoting the honor and success of the medical profession. The members from the South and West met those from the North aud East with a cordiality and a good-will which can be fully appreciated only by those who were present. Those who have not had the pleasure may be assured that nothing is needed to secure perfect unanimity throughout the whole profession of the United States than that they should act and feel toward each other as those do who have met this year face to face.

Absenteeism has done more than anything else to damage the Association and to alienate from it some of those whom it should love and honor, and who in their turn should contribute to its support and advancement True harmony will return whenever those who desire it take the trouble to come and meet their fellows in sincerity and with genuine good-will at the annual gatherings of a profession which should be at one in a country which is at one.

THE CHEST MOVEMENTS OF THE INDIAN FEMALE.

It has long been believed that a fundamental difference exists between the chest movements of females and of males during respiration: that the former breathe principally with the upper part of the thorax, and the latter principally with the diaphragm —this difference being known under the names of costal and diaphragmatic or abdominal types of respiration. No one had, however, investigated this question in relation to the chests of persons whose bodies had not yet been dominated by tight dress and other constricting influences incidental to more modern life until very recently, when Dr. Mays of this city made a number of observations on the chest movements of the Indian girls at the Lincoln Institution, the results of which, with specimen tracings, are published in the *Therapeutic Gazette* for May 15, 1887. From these experiments it appears that the Indian female, unlike our civilized female, has a marked abdominal or diaphragmatic respiration, with but slight, if any, costal motion; showing that the abdominal respiration is common to man and woman in their primitive condition, and that the costal respiration of the civilized female is an acquired feature.

The question of the type of respiration, as Dr. Mays points out, has a most important practical value, especially in its bearing on the etiology of pulmonary consumption. This disease, in most instances, is undoubtedly engendered by a want of proper expansion of the lung apices. Is this inexpansi-

bility in the upper portion of the chests of these Indian girls a mere coincidence, or is there a causal relation between it and pulmonary consumption? Such a relation becomes quite evident when we take into consideration the fact of the alarming extent to which this disease prevails among those very Indian tribes from whom these children are chiefly obtained.

Dr. Mays propounds the interesting question, whether the influence of the abdominal constriction, which is practiced by our civilized female, is detrimental to the respiratory organs, or whether it has a tendency to produce compensatory activity in the upper portion of the chest, and in conclusion asks whether there is any logical relation between the assumption that it develops the lung apices, and the fact that proportionally a less number of females than males die of pulmonary consumption.

THE THERAPEUTIC EFFECTS OF SILICATED MINERAL WATERS.

Dr. Macario calls attention in the *Journal d'Hygiène* for May 19, 1887, to the results of the labors of MM. Hugues and Baranger, in experimenting, during the past seven years, with the silicated waters of Sailles-Bains: Of 1,023 cases of skin diseases, 568 were cured, 328 improved, and 127 were not affected by the treatment. Of those afflicted with ulcers, obstructions, and the catarrhs of chronic metritis, there were 96 recoveries, 84 improved, and 20 negative results. Similar results were obtained in cases of Bright's disease, diabetes, rheumatism, dyspepsia, etc.

The beneficial action of these waters is accounted for by their sterilizing effect upon microbes and disease germs, principally by the contained silicate of soda; it arrests or checks all fermenting processes, disinfects and deodorizes putrescent matters. Hence, these waters are highly recommended in disorders of the digestive tube, and in all abnormal conditions dependent upon parasitic propagation. Their use is therefore urged in hospitals both for internal and external administration.

BLACK TONGUE.

By this term is understood a brownish-black coloring of the dorsum of the tongue. caused by no ingesta, extending from the circumvallate papillæ nearly to the tip. The sides and the tip remain nearly normally colored. Such a case is described by Dr. v. Bock, in the *Deutsche Medizinal Zeitung* of May 16.

An artist, 32 years of age, with no subjective symptoms, was found to have such a tongue. The appearance is described as similar to that of the plush of a silk hat. Rubbed from behind forward, it looked smooth, like plush brushed the right way. Individual fibres, like hairs, one-third of an inch long, were detected. They were found microscopically to be enlarged, pigmented, and horny filiform papillæ. No cause was found for this affection. In some cases the phenomenon disappeared in a few months, whilst in others it lasted 6–20 years. The treatment consists in softening alkaline gargles and mechanical removal of the fungoid growth.

AMERICAN MEDICAL ASSOCIATION.

The thirty-eighth annual meeting of the American Medical Association was called to order in Central Music Hall at 11:05 a. m., Tuesday, June 7, by Dr. Charles Gilman Smith, Chairman of the Committee of Arrangements.

Prayer was offered by Dr. McPherson, pastor of the Second Presbyterian Church of Chicago.

Dr. Smith introduced Mayor Roche and welcomed the American Medical Association to Chicago.

Mayor Roche: "Mr. President and Gentlemen, Representatives of the Science of Health and Life: In the name of the citizens of Chicago, I welcome you to this city, distinguished for the large number of able and eminent members of the medical profession, and for the exemplification in all the avocations and pursuits of life, of the precept, 'Whatsoever thy hand findeth to do, do it with thy might.' Your mission—to preserve health and remove disease, to prolong life and make it a blessing—is a beneficent and noble one, worthy of all honor.

"The present generation has seen great progress in medical science, and the medical profession, I think, has kept pace with the other learned professions, if it has not even excelled them, in original investigations and practical discoveries for the benefit of mankind.

"When in health we laugh at the doctors, and sometimes enjoy a joke at your expense. But in sickness you are our hope and our refuge, and to the worn and wasted patient, just struggling back to life from the gates of death, you are like 'the shadow of a great rock in a weary land.'

"The interchange of ideas and experience,

and the discussion of theories and experiments by large bodies of educated men, gathered from different and distant sections of the country, by which the individual thoughts and knowledge of each become the common property of all, is a comparatively modern outgrowth of society, and must contribute greatly to the interest and usefulness of the medical profession, being full of promise for the future.

"The official representative of a great and hospitable city, whose latch-string is always out, I emphasize the welcome of Chicago to this large, intelligent, and representative convocation of a profession whose chief occupation is to *save* life and not *destroy* it, and whose cardinal doctrine is that a sound mind in a sound body is essential to the best performance of the duties of this life, and a great help in fitting men for the life hereafter."

The Chairman then introduced Dr. E. H. Gregory, of St. Louis, President, who addressed the Association, concluding as follows:

"The painful part of the retrospect of a year is that which recalls those who have been taken from us. The past year has had a very special grief for our Association in the death of one of our ex-Presidents, Dr. William Owen Baldwin, who died at his residence, and the place of his birth, Montgomery, Alabama, May 30, 1886. He was among the early members of the American Medical Association, and its President in 1869, residing at New Orleans. His address on that occasion will be remembered as abounding in Christian and patriotic sentiments, eminently befitting the good and great physician. The committee charged with the organization of the Ninth International Medical Congress, which meets at Washington City this year, had named him as one of its Vice-Presidents. Dr. Baldwin was remarkable for his culture, the eloquence of his speech and the beauty of his diction, and will be remembered as an imposing figure in the history of this great Association.

"I need scarcely remind you, gentlemen, that we shall have with us, after a few weeks, the medical men of all nations. Soon we shall extend the hand of fellowship to those with whom we have heretofore been united in interest and sympathy in the cause of science. We know that everything is made ready and that success is assured. Again, you will join me, I know, in the delaration that a hearty American welcome awaits their advent, and that the Ninth Meeting of the Great Congress will be memorable in the history of its organization."

SURGICAL SECTION.

The Section was called to order at Central Music Hall, at 3 p. m. Owing to the absence of Dr. Mudd, Chairman, A. M. Pollock, Secretary, presided, and Dr. H. O. Walker, of Detroit, was appointed temporary secretary.

Thos. O. Summers, of Jacksonville, Fla., was not present, and his paper, "Cerebral Abscess," was referred to the Committee on Publication.

S. S. Armstrong, of Memphis, Tenn., read a paper on "Trephining in a Case of Intermeningeal Hæmatoma with Hemiplegia." In the discussion of the paper Dr. Walker, of Detroit, agreed with the author as to the importance of surgical interference in injuries to the brain, and reported the following case: In February a man was brought to the hospital as drunk, without further history. He was found to have paralysis of the left arm and leg, with incontinence of urine, pulse about 40, no increase in temperature. He remained in this condition five days, at which time trephining was resorted to. The trephining was done over the right fissure of Rolando, two buttons of bone removed, and four ounces of coagulated blood from between the skull and dura mater. The third day following the operation the patient informed him that the day before coming to the hospital he fell from a scaffold, striking on his feet; after remaining at work two hours he started home, and felt his left hand, in which he had his dinner pail, become numb. Shortly after he become unconscious, and remained so until after the operation. A rapid recovery was made.

Dr. W. C. Wile, of Philadelphia, read a paper on "Surgical Notes from the Case Book of a General Practitioner."

Dr. E. A. Wood discussed an "Unavoidable Deformity and Disability," which followed "Certain Outward Foot Dislocations." The outward foot dislocation at the ankle-joint was followed by the following deformity: Enlargement of the distal tibial end, increased prominence of the internal malleolus, increased malleolar space, outward version of the foot, the foot axis presenting outside the leg axis, tenderness in and about the ankle-joint, pain when weight was borne on the foot, and inability to walk unaided. The affection is often charged to carelessness by both surgeon and patient. The deformity often requires prolonged treatment, even for two years.

SECTION ON MEDICAL JURISPRUDENCE.

Judge Arnold Hull, of New York, read a paper on "Medical Jurisprudence in its Relations to Undue Influence as Affecting Wills and Contracts." He defined undue influence to be fraudulent persuasion or oppressive and irresistible importuning, or adroit deceit imposed on a mind impaired by disease or infirmity, which induces the making of a testamentary instrument or a contract which would not have been made had the mind been true and in its normal condition, and cited cases illustrating the character of undue influence very fully.

Dr. S. B. Reeve, of Baltimore, discussed at length the medico-legal bearings of undue influence. He cited the instance of a man who had used undue influence, through pretended affection, over an old colored woman to secure her property. In this case the will was set aside.

Dr. Buckham said it was not the province of the judge to give definitions. It was impossible to give exact definitions. Persons could be insane on one point. They might have delusions and yet not be insane.

Dr. Kiernan was of opinion that there was no such thing as a person insane on one point and having but one delusion. The insanity was in the man, not in the delusion. Undue influence was not easily proven to be exerted. Supposing a female erotic from the climacteric left her property to a person who pretended to love her, could this influence be legally said to be undue? A will was more likely to be a perfectly sane performance than a murder. The burden of proof should not be in favor of the party opposing the will. Insanity was a relative, not an absolute term.

Dr. Spitzka alluded to the influence of hypnotism in tending to cause undue influence, and cited Charcot and Babinski's recent experiments in illustration. Insanity was a general, and not a local disease. Strictly partial insanity did not exist.

"Suppression of the Illegal Practice of Medicine" was read by title.

SECTION ON MEDICAL JURISPRUDENCE.

Dr. Frank S. Billings, Director of the Patho-Biological Experiment Station of the State University of Nebraska, read a paper on "The Necessity of a Uniform Standard of Education in all American Medical Schools."

The author is directly opposed to the existing system of medical education, and finds nothing worthy of praise as it now is. The professional results that have been creditable to American medicine have been due more to influence outside the schools than to the schools themselves.

The great variation in the course of instruction in the different medical schools is compared, the standard being 56 at the last annual report. The actual number of days attendance upon lectures required varies between 18 and 621 days; this is after deducting Sundays and holidays. In Missouri, out of eight regular schools, the course varies from 224 to 381 days, in New York, from 190 to 621 days.

The following couclusions terminate his paper:

First.—No uniformity can be had in forensic action until some method is devised for bringing the regular medical schools into line and inaugurating one system of instruction and one system of graduation in them all.

Second.—Forensic medicine must become a specialty for both medical and legal experts, both of whom must take a full course in medicine and law.

Third.—The desired ends can be best obtained by inaugurating a course for the medical schools in the different parts of the country by the general government, which shall support them; one system of education and one system of graduation dominating these schools. There should also be a national school of comparative medicine, to be the chief point of original research and medical education in the land.

Fourth.—The inauguration of a course of instruction in pathological anatomy and general pathology in all schools.

Fifth.—The condemnation by the American Medical Association of all medical schools not requiring a 3 years course of study of 9 months each.

OBSTETRICS AND DISEASES OF WOMEN.

Dr. Morris in his paper on "Placenta Prævia" said that three fatal cases of placenta prævia that had recently come to his notice, two of which he had seen in consultation, convinced him that some more positive and radical views of treatment should be adopted in this grave trouble than those suggested in the text-books of the day.

Dr. Morris laid down the following propositions:

1. No expectant plan is justifiable in cases of placenta prævia. The uterus must be emptied as soon as possible after the discovery of the trouble, no matter what the stage of pregnancy may be. A halting, hesi-

tating practice means danger both to mother and child.

2. That the life of the child must not be considered in the treatment of the case.

3. That the manner of emptying the uterus must be left to the individual judgment of the medical man in attendance.

4. That in cases of central adherence of placenta the safest and best practice is to separate the placenta entirely.

5. That in cases where the placenta is adherent in the latero-cervical zone of the uterus, partial detachment may be sufficient; but if the hæmorrhage is not arrested, the whole mass should be removed and means of delivery at once instituted.

6. That the colpeurynter is the only tampon that can be safely used in these cases—that sponges, silk handkerchiefs and other forms of tampon are nasty, filthy and septic, and should never be employed.

7. That the bi-manual treatment, whenever possible, is the best and the speediest form of delivery.

8. That chloroform must be administered in all cases in which manual interference is necessary.

In discussing these propositions, Dr. Morris said that there is no emergency in obstetrics so dangerous, and in which skill, judgment and energy are so necessary, as hemorrhage resulting from placenta prævia. Statistics show that the maternal mortality in these cases is from twenty five to forty per cent. Of the four cases that had last come under his notice, all in consultation, three proved fatal---two from septicæmia, on the fourth day, and the third from sudden and uncontrollable hemorrhage. The fourth case, which recovered, was treated by a pupil of his own, who had lived in the Maternity Hospital, Vienna, for two years, and was thoroughly acquainted with the procedures of that school. He dissented from Dr. Parvin's recommendation of delay or palliative measures in these cases. Patients die from two causes, anæmia and septicæmia. Septicæmia becomes essentially fatal in the presence of anæmia. The anæmia is the result of the repeated hemorrhage permitted to take place under the expectant plan of treatment.

Statistics show that in cases of placenta prævia two-thirds of the children perish before the full term, and of those that are born alive one-half perish soon after birth; therefore, considerations of humanity would lead us to think only of the safety of the mother; indeed, in adopting measures for her speedy delivery, without regard to the safety of the child, more children would be saved in the end.

The manner of emptying the uterus must be left, as before stated, to the individual judgment of the practitioner.

The colpeurynter answers many purposes: it serves to arrest hemorrhage by the pressure it exercises; it softens the cervix and leads to gentle and gradual dilatation of the os; it relaxes the vagina and soft parts, and thus prepares the way for the use of dilators, such as Molesworth's or Barnes' bags, or even the fingers, if practicable. The colpeurynter should be filled with hot water—hot as the patient can bear; this should be renewed every hour.

Colpeurysis is, he said, little known to the general profession. It is only those gentlemen who have been educated in Germany, particularly Vienna, who are acquainted with its remarkable usefulness. There is no other means so valuable in the induction of premature labor.

Dr. Hiram Corson, of Pennsylvaia, read a paper on

ABORTION,

stating that it was his practice when there was hope of saving the embryo to rely on the use of anodynes to relieve pain and prevent contraction of the womb, but when he believes there is no hope of saving it and miscarriage will occur, he uses the sponge tampon in the vagina to prevent excessive flooding, and opium for its effect upon the nervous system, and then waits sometimes months, until the mouth of the womb shall open sufficiently to enable the removing of the ovum with the fingers.

He believes early dilatation by tents and forceps to be dangerous, and never uses them, while with the treatment spoken of he has never lost a patient or known of any other physician losing one.

He never has used antiseptics, and does not believe there is danger of septicæmia from absorption of putrid blood. Deaths not infrequently occur from the use of tents, causing metritis and peritonitis, and these can not be attributed to absorption of putrid blood.

He thinks the washing out of the vagina and womb with antiseptic fluids after the miscarriage unnecessary, annoying, and sometimes harmful to the patient.

The author stated the principal object of his paper was to prevent the meddling with abortion cases that is likely to result from the teachings of the day, especially the use of tents and forceps, which have proved dangerous to the mother.

Notes and Comments.

Irish Moss as a Substitute for Gum Acacia in Pharmacy.

Peter Boa has found that by using a hot-water funnel and straining a mucilage of Irish moss through absorbent cotton wool supported on muslin, a preparation clear enough for all but exceptional purposes could be obtained with comparatively little difficulty. If a perfectly water-clear preparation be required, it may be obtained by making a weak mucilage, filtering it clear, and then evaporating to the required consistency. The mucilage is prepared by digesting ¼ oz. of washed moss in 24 oz. of water for an hour, boiling for five minutes, and straining the moss mucilage. It serves as well as acacia for chalk mixture; guaiac mixture prepared with it has not so green a color as that made with acacia. For suspending copaiba it is superior to acacia. Separation takes place much more slowly and less completely. Part of the copaiba remains in an emulsified state at the bottom of the bottle when moss is used, but with acacia the whole rises to the top. For emulsifying cod-liver oil it is greatly superior to acacia for preventing separation, but finer division of the oil is obtained with acacia. Moss mucilage ʒvj., cod-liver oil ʒj., and water ʒij., produce an emulsion that does not readily separate. Using ʒvj. acacia mucilage, ʒj. cod-liver oil, and ʒij. water, the resulting emulsion soon separates. It is *not* adapted for suspending heavy powders, such as bismuth subnitrate. The mucilage keeps well in full bottles.—*The Chemist and Druggist, May* 14, 1887.

Practical Notes.

Collodium antisepticum, which may be used like ordinary cotton, is recommended (*Journal de Médecine*,) to be prepared from powdered mastic 3 parts, powdered narcotine 1 part, balsam of Peru 1 part, and chloroform 5 parts. Strips of linen or silk soaked in this solution, form an excellent adhesive plaster.

Oleum cinereum is a mercurial preparation used by Dr. E. Lang in syphilitic complaints. It is prepared by triturating, in a cool place, lard, oil, and mercury, until the latter becomes uniformly suspended, the finished preparation to contain 20 per cent. of the metal. It is used as a local dressing; also as an injection to enlarged glands, 0.01 to 0.02 cc. being given once a week or in a fortnight. For use it is melted by the warmth of the hand.

Unguentum cretæ præparatæ is recommended by Dr. Dyce Duckworth as an application in erysipelas. It is prepared from equal parts of prepared chalk and lard, and to each ounce of the ointment is added 30 grains of carbolic acid. An equally serviceable ointment is obtained with precipitated calcium carbonate, and this is of a pure white color.

Absorbent wool, a by-product in the manufacture of wool-fat or lanolin, is coming into use as a substitute for absorbent cotton, over which it is said to have the advantage of greater absorbing power for liquids, and of much greater elasticity.

Eye Troubles Due to Chloral.

"In the January number of the *Alabama Medical and Surgical Journal*, Dr. Wm. Cheatham reports two cases of eye disease in which the use of chloral produced severe photophobia. Dr. C. thinks that the keratitis and choroiditis are due, in part at any rate, to the use of chloral. He has seen several persons in whom one dose of chloral of fifteen grains would produce marked hyperæmia of the conjunctiva, with photophobia." So says the New Orleans *Medical and Surgical Journal*, and asks for the report of cases. A case is under our notice at the present time. Great photophobia was complained of, but we did not think of the chloral as a cause. Large doses had been given while the patient was in a maniacal condition. On coming to himself, he complained of the eyes, and there is now no doubt that it was due to the chloral. This observation of Dr. Cheatham's is a most practical one, and we should like to call the attention of physicians to it, and to ask for reports of all similar observations. We should also esteem it a favor if the oculists whose eyes meet with this paragraph would give the general profession the benefit of their experience.—*Pacific Medical and Surgical Journal, May*, 1887.

Fluid Extract of Ergot in Internal Hemorrhoids.

Dr. Jervy, of Virginia, some six years ago, called my attention to the good results that followed the injection of fluid extract ergot into the cavity of the rectum in internal piles. He said some doctor in Richmond, whose name I do not recall, read a paper on the subject, and that he had found it good, etc.

Of eight bad cases of internal piles, such as I had formerly immediately advised operative procedure in, *six*, treated with one drachm fluid extract ergot, in same quantity of hot water, injected twice a day, morning and evening, so far recovered that there were no tumors left to excise or tie. The injections were not made in the substance of the tumors, but simply with a p. p. syringe, thrown up and retained in the rectum. In some cases it produced so much uneasiness that it was soon voided. The addition of ten drops of laudanum to each injection secured toleration. This practice cheats the surgeon, but as patient and physician are a majority, his protest in a democratic community will not be considered. Of course this agent will not cure all cases, but six out of eight is a pretty good record.—*Dr. Todd, in Atlanta Medical and Surgical Journal, June*, 1887.

Danger in Santonin.

Danger in santonin, even when given in moderate doses, was reported some weeks since in the *Lyon Médical* to have been observed so frequently that the matter has been inquired into by the *Rép. de Pharm.*, with the following results: The white santonin was found more toxic than that which had become yellow through exposure to sunlight, though the latter did not show any diminution in its therapeutic properties. Lawre thinks that the dose for a child of less than two years should not exceed three-fourths of a grain. In all cases it should be associated with a purgative—calomel, for example—to facilitate its elimination. "Santonin is innocuous or toxic," he says, "in proportion to the rapidity with which it may be eliminated, and this varies in individuals." Lewin and Caspari recommend that it be administered in oily solution. In this form it is absorbed by the intestines slowly enough to permit a direct and prolonged contact with the worms. — *Journal of Pharmacy, June*, 1887.

Perfumery as a Sedative.

Dr. Watson Smith, London, reports the case of his own boy, critically sick with dysentery, and the stomach so sensitive that vomiting was excited immediately any attempt was made to administer anything. The doctor then thought of the sedative effect of perfumery, and argued that, if he could so deceive the patient as to cause the imagination to attribute to the article administered the delicate flavor of the perfumery, the effect upon the olfactory nerves would be soothing upon the nerves of the palate and stomach.

Some simple diet was given in a spoon held with a handkerchief upon which a delicate perfume was sprinkled. The effect was excellent, and after a short time medicines could be given in the same way, and were retained without further disturbance of the stomach, and the patient rapidly recovered.

This plan of masking the sense of taste through the influence of perfumery upon the olfactory nerves may be equally pleasant to adults.

Advantages of Cinchonidine.

M. Legenis, in an elaborate paper in the *Archives Génerales de Médicine*, details the results of careful and extended observations on the action of cinchonidine and its salts on the various forms of intermittent fever. His conclusions may be briefly summarized as follows:

(1) That the salts of cinchonidine are as efficacious as those of quinine.

(2) That they may be employed in all cases in which the latter are generally used.

(3) That the sulphate of cinchonidine is well tolerated by the stomach in nervous persons or in those intolerant of quinine, and that it does not produce either ringing in the ears, nervous agitation, or tremors.

(4) That the cost is about half that of quinine and its salts.

Nitrite of Amyl in After-pains.

Mr. F. Wellesley Kendle, of South Molton, describes in the *Lancet* a case of excruciating after-pains, worse than any during labor, in which he broke a couple of nitrite of amyl capsules (4 grains in each) into a smelling-bottle, and directed the patient to take two or three inhalations when she felt a pain coming on. The effect was simply magical; the pains were immediately relieved, and shortly ceased altogether, the patient being soon able to take some refreshing sleep. She quickly made an excellent recovery. Two other cases of less severity had similar results, and it was found invaluable in the sickness of pregnancy and in obstinate cases of dysmenorrhœa, without a single failure or bad result.

Method of Inducing Respiration.

Dr. Enos Blackwell reports a method of resuscitating the new-born infant when in an asphyxiated condition. It has one very decided

merit, that of immediate application, but is, as Dr. Blackwell says, a procedure which embodies the principles of the Marshall Hall method. The child is laid on the palms of the accoucheur's hands, and then rapidly tossed with a quick motion, this being done while the placenta is still attached. The rapid movement makes the arms fly up, thus lifting the chest walls, and the infant takes air with a sudden sob. Although a rough and ready method, the author has found it highly successful in many instances.—*Weekly Medical Review.*

Spurious Venereal Diseases.

Mr. Jordan Lloyd, after a careful study of the subject, arrives at the following conclusions concerning spurious venereal diseases:

1. That a large number of urethral discharges in the male, although sexual in their origin, are not specific.

2. That many penile sores of sexual origin are neither chancres nor chancroids.

3. That idiosyncrasy plays an important part in the contraction of venereal diseases of all kinds.—*Birmingham Medical Review.*

Diuretic Wine.

The celebrated "Vin Diuretique, Hotel Dieu," as devised and frequently used by the great Trousseau, has this composition:

℞.	Digitalis,	part	v.
	Rad. scilla,	"	viij.
	Juniperis,	"	lxv.
	Potassii acetatis,	"	l.
	Alcoholis (90 per cent.)	"	c.
	Vini albæ,	"	dcccc.

M. The squills, digitalis and juniper berries are to be broken up, and macerated for two weeks in the alcohol and wine, the mixture being frequently stirred. At the expiration of the fortnight, it is be pressed, strained, the acetate of potash added, and the compound filtered, when it is ready for use.

A Point in the Treatment of Chorea.

Dr. Flood, of Minnesota, says that he has almost constantly found tenderness on pressure over the fifth cervical vertebra in choreic cases. In these he applies the ether spray over the tender spot, and follows that with a mild counter-irritant. Then with a judicious use of tonics and ergot he has generally been successful in the treatment.—*Chicago Med. Times.*

A Sedative Solution.

Solution of magnesium bromide, a preparation largely used in the Philadelphia Hospital by Dr. Da Costa and others as an effective sedative without any untoward effects, is recommended by Jos. W. England (*Am. Journ. Pharm.*, p. 531), to be prepared as follows: One pint of diluted hydrobromic acid (U. S. P.) is saturated with magnesium carbonate (about one troy ounce being required). Each fluidram contains seven grains of anhydrous magnesium bromide.

Salol in Sciatica.

Dr. V. Aschenbach, of Corfu, reports in the *Fortschritte der Medezin*, that, suffering from sciatica, for which all known remedies have been tried in vain, he at last resolved to try an unknown one—to himself, at least, unknown as a remedy for sciatica. In the evening he took a dose of 7 grains, and at midnight 15 grains, after which he fell asleep, and remained perfectly free from his pain.

Socotrine Aloe Leaves for Burns.

One of the thick aloe leaves is split in half, and the fresh inside portion is applied to the burn. The pain disappears instantly. The green juice of the plant turns violet, and all traces of the burn often disappear by the next day, except a violet tinge, which may remain for ten or twelve days.—*Le Monde Pharmaceutique.*

Apomorphine.

Rossbach recommends this as an expectorant, in combination with morphine:

℞.	Apomorph. hydrochlor.,	gr. ¾.
	Morphinæ hydrochlor.,	gr. ½.
	Acid. hydrochlor. dil.,	♏ viij.
	Aquæ,	℥ v.

Dose.—A teaspoonful every two to four hours. To be dispensed in a black or other non-actinic glass vial.

Talc Dentifrice.

Vigier (*Jour. de Méd. de Paris*) recommends the following dentifrice:

℞.	Talc,	2 ounces.
	Cream of tartar,	78 grains.
	Burnt alum,	78 "
	Cochineal,	156 "
	Essence of mint,	20 drops.

M. Powder carefully and finely. S.—Use as a dentifrice.

Amorphous Borate of Quinine.

The *Rundschau* states the medicinal action of two such powerful antiferments as are combined in amorphous borate of quinine is not such as was expected, and that its difficulty of administration and uncertain action will soon render it obsolete.

CORRESPONDENCE.

Colored Fires.

EDS. MED. AND SURG. REPORTER:

Can you furnish me some formulæ for combining drugs so as to make colored fires? To be answered in the MED. AND SURG. REPORTER. Yours,

L. M. FOCHT, M. D.

Lockport, Ill., June 1, 1887.

[In view of the fact that the Fourth of July is approaching, we are glad to respond to this query, although its tenor is not strictly medical. The formulæ are here presented through the courtesy of Mr. G. M. Beringer, Ph. D., of this city.—EDITORS OF THE REPORTER.]

1ST.

Red.—10 ounces strontium nitrate, 6½ ounces sublimed sulphur, 1 ounce powdered charcoal, 3 ounces powdered chlorate of potassium.

Green.—9 ounces barium nitrate, 3 ounces sulphur sublimed, ½ ounce powdered charcoal, 3¾ ounces powdered potassium chlorate.

Yellow.—12 ounces powdered sodium nitrate, 3¾ ounces sublimed sulphur, ¾ of an ounce powdered charcoal.

Blue.—2 ounces ammoniated copper, 4 ounces sublimed sulphur, 8 ounces powdered potassium chlorate.

2D.

Red.—4 ounces strontium nitrate, 1 ounce pulverized shellac, 1 ounce pulv. potassium chlorate.

Green.—4 ounces barium nitrate, 1 ounce pulverized shellac, 1 ounce pulverized potassium chlorate.

Yellow.—6 ounces pulverized sodium nitrate, 2 ounces pulverized shellac, 2 ounces pulverized chlorate of potassium.

The first set of recipes are for the ordinary sulphur and charcoal powders. The second call for shellac in place of sulphur and charcoal, and are considered the best.

The Diffusion of Rational Medicine and Liberal Views.

We print below an interesting note just received, and commend to our readers the plan advocated. — EDITORS OF THE REPORTER.

"TEHERAN, PERSIA, *April* 23, 1887.

* * * * * * I send you a copy of the *Echo de Perse*, published at Teheran, and enclose a translation of a notice of the hospital, for the erection of which permission has been granted by the Shah. You are at liberty to publish any or all of the article in your valuable REPORTER, and will be pleased, I'm sure, to know of our prospects here.

"We would be many times obliged if a plea could be made for the hospital. We need $10,000 to put up buildings, baths, house for resident physician, etc., and I have asked our Society to allow me to ask for $5,000 for immediate needs."

Translated from the *Echo de Perse* of April 15, 1887:

"We learn with great pleasure that by Imperial firman, His Majesty, the *Shah in Shah*, has authorized the American missionaries to establish, at Teheran, a hospital, where, without regard to religion or nationality, all seeking relief shall be received for treatment. Dr. Torrence, physician to the mission, has been appointed Director of this establishment, which is destined to render great service to our cosmopolitan population.

"His Imperial Majesty, desiring at the same time to reward the zeal and devotion of Dr. Torrence, who for long years past has been gratuitously relieving so much suffering and distress, has named him Grand Officer of the Order of the Lion and Sun of Persia."

A Note from Alabama.

EDS. MED. & SURG. REPORTER:

* * * * * We are astir now on the subject of quarantine. A letter from Dr. Holt, President of the Board of Health of Louisiana, to Gov. Perry of Florida, was referred to me as President of the Medical Asssociation of Alabama, and *ex-officio* President of the Board of Health of this State till April, 1888, to refer to our local board of health for action in reference to necessity of rigid quarantine at Tampa and other Florida ports, it having been ascertained that parties direct from Havana, where yellow fever is prevailing, had passed into the interior without detention. By action of our local board Gov. Perry was written to, Dr. Holt's views being endorsed. Dr. Jerome Cochran, our State Health Officer, has been notified by me, and will visit the quarantine stations below us to see how effectual they may be to prevent us from suffering an invasion of yellow fever, and perhaps the worse pestilence, cholera. We are satisfied that now, the danger be ing known, great care will be taken, and the avenues of approach guarded.

Yours truly, E. H. SHOLL, M. D.

Birmingham, Alabama, May 30, 1887.

Novelties in Hypodermic Medication.

[A valued, but too modest, correspondent in Pennsylvania scores a good point in the following note. If any of our ingenious readers have hit upon new devices and useful "wrinkles," in the use of medicines hypodermically, we all want to know of it. We shall do our part, and give some useful working formulæ.—EDITORS OF THE REPORTER.]

* * * The REPORTER I like greatly, and renew herewith for one year. I wish you would have an article, or several articles, on the hypodermic use of medicines, the way to prepare the same for use, and dose, etc. There are new things coming into use which, if one does not see used, one is often at sea to tell how to use the same. One will read a most learned article about the efficacy of some new drug, without the preparation, dose or mode of administering being even mentioned. For a country physician these are all-important, as we do not have the opportunity to call in and see the physician who has become familiar with its use. I feel sure that to give a full description of the preparation of medicines for hypodermic use will be very instructive to us countrymen.

NEWS AND MISCELLANY.

Yellow Fever at Key West.

The following official report from the Supervising Surgeon-General of the U. S. Marine Hospital Service is just received:

The medical officer in charge of the Marine Hospital Service (Passed Assistant Surgeon Glennan), under date of May 28, reports that "out of a total of 5 cases there have been 3 deaths and 1 recovery, and 1 with a probability of recovery," from yellow fever, "all originating in one infected premises. The danger apprehended was on account of the large number of unacclimated persons in the city, with every means of outlet cut off. Many left in sailing-vessels, and, at my suggestion, Dr. Porter asked the Louisiana Board to allow healthy persons to go from here this week, subject to inspection or detention at the New Orleans quarantine, which was granted. At this date no new cases have developed, but it is yet too early to say that the disease has been stamped out. In any event, the care exercised in this instance by the Board of Health in guarding infected houses, fumigating and destroying infected material, and in promptly declaring the existence of the disease (measures probably for the first time efficiently adopted in this place), has practically established an outside confidence in sanitary information emanating from here. * * * It is reasonable to suppose that the infection was introduced here by a Bolio family, who formerly kept the San Carlos and Fifth Avenue hotels in Havana. During the past winter they have brought over household goods and stored them in the adjoining house. It is said that Baker and his wife slept upon one of their mattresses. At a special meeting of the Board of Health this morning, at which I was present, this was recognized as probable. The disease may now be said to have three foci; and should the Board of Health now succeed in preventing its further spread, it will only be done by the utmost care and vigilance."

A telegram, June 1, reports 4 new cases in different localities.

The War Department authorized the president of the Board of Health to use the hospital and the laundress quarters attached to the military barracks for the treatment of yellow-fever patients. Iron bedsteads and mattresses were sent from the marine hospital stores.

The United States sanitary inspector at Havana, Dr. Burgess, reports that the furniture bought of Mrs. Bolio and used by the Baker family had been used in a hotel at Havana, and it is well known that many cases of yellow fever had occurred in that hotel during the last few years. He himself had treated 5 cases in it, and is of opinion that the old pillows, bedding, etc., were the sources of infection.

Pennsylvania State Medical Society.

The thirty-eighth annual session of the Medical Society of the State of Pennsylvania will be held at the Bedford Springs, June 29, 30, and July 1st, 1887. The following papers are to be read: Address on Surgery, Dr. J. B. Murdoch, Pittsburgh; Address on Ophthalmology, Dr. Chas. S. Turnbull, Philadelphia; Report on Hydrophobia for 1886, Dr. Chas. W. Dulles, Philadelphia (request of Society, see page 31 of Transactions, 1886); Medicated Plasters in the Treatment of Diseases of the Skin, Dr. John V. Shoemaker, Philadelphia; Remarks on the Value of Diet in the Treatment of Chronic Joint and Spine Disease, Dr. A. Sidney Roberts, Philadelphia: Address on Practice of Medicine, Dr. Frank Woodbury, Philadelphia; Palatable Therapeutics, Dr. Traill Green, Easton,

Pa.; Iodoform in Surgery, Dr. Geo. Stubbs, Philadelphia; The New Methods in the Treatment of Phthisis, Dr. W. F. Waugh, Philadelphia; Address on Obstetrics, Dr. S. Wolfe, Skippack, Pa.; Report of a case of Right Inguinal Colotomy, Dr. John H. Packard, Philadelphia; Two Cases of Nystagmus, Dr. Wm. C. Bane, Washington county; The Salient points in the Treatment of Pulmonary Consumption, Dr. T. J. Mays, Philadelphia; When and How to use Mydriatics in the Eye, Dr. Edward Jackson, Philadelphia; Plastic Surgery of the Vagina, Dr. C. M. Wilson, Philadelphia; Annual Address by the President at court-house, Bedford, Pa., Dr. R. Davis, Wilkes-Barre; Address on Mental Disorders, Dr. J. Z. Gerhard, Harrisburg; Ovariotomy followed by Herniotomy four days after—recovery of patient, Dr. John C. DaCosta, Philadelphia; Some consideration upon the use of Expectorants in Pulmonary Diseases, Dr. J. C. Lange, Pittsburgh; Ovarian Tumors Complicating Pregnancy, Dr. E. E. Montgomery, Philadelphia; Suprapubic Lithotomy, Dr. Chas. W. Dulles, Philadelphia; Address on Hygiene, Dr. J. D. Thomas, Pittsburgh; Remarks on Vomiting, Physiological and Clinical, Dr. J. H. Musser, Philadelphia; Abdominal Hysterectomy with specimens, Pyo-salpinx with specimens, Fibroid Ovary, Sarcomatous Ovary, Dr. Howard A. Kelly, Philadelphia; Modern methods in the treatment of Pulmonary Consumption, Dr. S. S. Cohen, Philadelphia.

Medical Expert Testimony.

The *Lebanon Gazette*, May 26, 1887, contains a paper by F. H. Darby, M. D., on the proper status in court of medical experts, in which he expresses the following opinions:

A witness to fact in court is an individual simply in possession of knowledge of the case at issue acquired by the natural exercise of one or more of the five senses. That it is the duty of such witness, under certain rules and statutory requirements, to communicate the same, is well understood.

The medical profession, by reason of its close intimacy with the affairs of life, does more of this work per capita than any other. Physicians become cognizant of more facts than men in any other calling. To attend courts and communicate the same is the duty of all good citizens. The medical profession is now, as it ever has been, distinguished for its patriotic devotion to duty. Doctors, as a rule, are unselfish citizens, ever ready for any good work. As citizens and tax-payers they claim no immunity from the duties incumbent on their fellow-citizens.

But expert testimony calls for the surrender of what only the members of a special class can possess—what is, in fact, their stock in trade, what they usually sell, and what has cost them years of valuable time and thousands of dollars to obtain. Its disposal is their only resource—their means of earning a livelihood.

Between such a class of persons and jurymen there is no analogy; any one can serve on a jury, the more ignorant the better, while it takes an individual previously and specially educated and skilled to be of any value as an expert.

The labor of an expert, making plain and intelligible to the court and jury some scientific problem, is exactly analogous to that of an interpreter, a lawyer, a referee or master, all of whom receive good pay for their services.

That our professional knowledge is property, is admitted by all; that it should always be held subject to use by the courts of justice is a correct principle; but to use this or any other property for the public good without reasonable compensation, is an injustice.

The Consulting-room.

Dr. Dubray has recently published some instructive and amusing advice to a beginner in the medical profession. Dr. Dubray distinguishes four kinds of consulting-rooms: the unpretentious, the surgical, the artistic, and the encyclopædic. They are not peculiar to France. In the unpretentious consulting-room the furniture is plain, the bookcases small, and there are just sufficient tables and chairs to allow the patient to sit down and the medical man to write a prescription. The surgical consulting-room presents instruments and appliances scattered about in an apparently artless manner. Dr. Dubray thinks that, except in the case of a surgeon of admitted renown, an exhibition of this kind is in bad taste. We, however, quite agree with the *British Medical Journal* that *all* such exhibitions are in bad taste. Complete abstention from parade of instruments is the best rule. It is not advisable to leave hypodermic syringes about the table, with specula serving as paper-weights. These instruments should not be made into advertising agents any more than the herb-doctor's tape-worms and fœtuses in alcohol. Even the gynæcological couch should be kept in a corner, and not placed well in the light,

showing off its supply of steps and elevating mechanisms. Such practices savor too much of the crocodile which hung from the ceiling of the alchemist's laboratory.

"Specialism in Excelsis!"

The *Lancet* of May 21, 1887, amuses its readers with the following thrust at an American Society:

"We have received a programme of the first annual meeting of the 'Association of Genito-urinary Surgeons,' which is being held this week at the Laurel House, Lakewood, N. J. The establishment of this Association has been attended with so much success, and commends itself so thoroughly to the more enlightened members of the profession, that many similar ones are shortly to be inaugurated! Among those more immediately to be promoted are associations of 'Umbilicologists,' of 'Rhinologists,' of 'Tenotomists,' of of 'Depilatory Surgeons,' and of 'Skin-grafters.' The only reason we can perceive why this should not be indefinitely extended is that surgery as an art would, by such differentiation, speedily be resolved into its constituent elements, and its professors broken up into repellent groups of solemn deliberators on the utility and beauty of the segregation of parts."

This is all very funny, but if it had been held back until after the report of the meeting referred to, we think it would not have been published; for the objects of the Association of Genito-urinary Surgeons, as explained by the President, are so sensible, and the proceedings at its first meeting were so instructive, that it deserves to be encouraged, and not to be ridiculed.

Measures to be Taken to Prevent the Spread of Yellow Fever.

A telegram from Washington, D. C., dated June 4th inst., says: Surgeon-general Hamilton to-day received a telegram from the Governor of Florida as follows:

"Florida has no Board of Health. I hope you will give such aid as you can to local county boards to eradicate yellow fever in Key West and prevent its spreading to other localities."

Surgeon-general Hamilton replied by telegraph as follows:

"If the Legislature is in session, can they not pass necessary laws? Please state resources at your command. I am instructed by the Secretary of the Treasury to assure you of the full coöperation of the Department in supplementing State forces."

Dr. Hamilton also telegraphed Dr. J. P. Hall at Tampa, Fla., that the Post-office Department wants the mails fumigated, and that the Marine Hospital Bureau will assume all reasonable expenses incured in the fumigation.

The total number of cases of yellow fever at Key West to date is 13, of which 4 have resulted fatally. Six patients are sick and three convalescent.

Illness of Professor Billroth.

Prof. Billroth has been dangerously ill. He suffers from a fatty heart and great exhaustion. At one time his life was despaired of, and intense feeling was manifested, not only by the whole of the medical profession and the medical students of the city, but by leading personages throughout Europe, and telegrams were received from friends in all parts of the world, making anxious inquiries. We are glad to state that Professor Billroth's illness has taken a more favorable turn, and that he is now rapidly regaining his usual state of health.

The Climatological Society's Officers.

At the meeting of the American Climatological Society, June 1, the following officers were elected for the ensuing year: President, Dr. A. L. Loomis, New York; Vice-Presidents, Dr. A. Y. P. Garnett, Washington, and Dr. J. T. Whitaker, of Cincinnati; Secretary and Treasurer, Dr. J. B. Walker, Philadelphia; Councillors, Drs. E. T. Bruen, Roland G. Curtin, Philadelphia; J. H. Tyndale, J. F. Bosworth, New York; and Fred. C. Shattuck, Boston.

Hydrophobia.

The daily newspapers state that the four-year-old daughter of Greenberry Davis died on Sunday, May 29th, of hydrophobia, at Wood's Run, near Pittsburg. She was bitten by a dog about seventeen months ago.

[We would be glad to have some accurate and reliable account of this case, which is, we believe, the first one reported in the State of Pennsylvania for more than a year.—EDITORS OF THE REPORTER.]

The Association of American Physicians.

The Association of American Physicians, in session in Washington, elected officers for the ensuing year as follows: President, Dr. William H. Draper; First Vice-President, Dr. Francis Minot; Second Vice-President,

Dr. R. Palmer Howard; Recorder, Dr. William Osler; Secretary, Dr. Henry Hun; Treasurer, Dr. W. W. Johnston; Member of the Council, Dr. William Pepper.

Preserving Salts.

Paul Weferlingen, in *Phar. Ztg.*, recommends the following for preserving fish or butcher's meat during warm weather: (1) Common salt, 8 parts; nitrate of potash and salicylic acid, of each 1 part; (2) boracic acid, 30 parts, nitrate of potash and common salt, of each 35 parts. A preserving powder for tinned fruits is composed of salicylic acid, 5 parts; and powdered sugar, 95 parts. This is sprinkled over the surface, and may also be used for sprinkling over fresh fruit, such as strawberries, which have to be kept over night.

Professor Baird Seriously Ill.

Prof. Spencer F. Baird, Secretary of the Smithsonian Institution, is quite ill of an affection of the heart and kidneys. He left Washington for a rest and change of scene a short time ago, but, as it did him no good, he returned and is now in bed. A consultation was held on the case on June 1 by Dr. N. S. Lincoln, of Washington, and Drs. Mitchell and Osler, of Philadelphia.

Meeting of the American Otological Society.

The 20th annual meeting of the American Otological Society will be held at the Pequot House, New London, on Tuesday, July 19, 1887, at 10:30 a. m.

Items.

—"Disease" is the name given to one of the swift yachts of the Burlington Ice Yacht Club. The Disease must be a kind of running disorder—possibly mastitis.—*New York Medical Record.*

—Nebraska has established a State Board of Health, consisting of one graduated physician, of at least ten years' practice, from each of the seven congressional districts, and one at large, with the Governor as presiding officer.

—Dr. Hewson Bradford was recently elected by the Board of Managers of the Pennsylvania Hospital a member of the staff of the out-patient department, to fill the vacancy caused by the death of Dr. Elliott Richardson.

—H. W. Stevens and W. J. Spencer engaged in an eating match in Salem, Ill., last week. The match was to see which could increase his weight most by eating. Spencer increased his weight by six and a quarter, and Stevens by six and a half pounds.

—Investigations into the spread of tuberculosis among the blooded cattle at the Rhode Island State Farm have culminated in the extinction of the herd of sixty cows, and sixteen draught cattle exposed will be killed in a few days. The loss to the state will be $7,000.

—The season of the Sanitarium has been formally opened on Thursday, June 2d, on the new grounds at Red Bank, New Jersey. The new site comprises 83 acres of land, with two large brick buildings, a shaded park of twelve acres, with a river front of over 800 feet.

—The mortality of the entire globe, as given by a continental journalist who has made the computation, is as follows: Per minute, 67; per diem, 97,790; and per annum, 35,639,835; whereas the births are 36,792,000 per annum, 100,000 per diem, and 70 per minute.

—Dr. George de Schweinitz has been chosen as an additional ophthalmological surgeon in Philadelphia Hospital by the Board of Charities and Correction. Dr. de Schweinitz is already consulting oculist at the Orthopœdic Hospital and the Children's Hospital and Dispensary.

—There has been but one May as warm as the one that is just over for sixteen years, and perhaps longer; and people curious about weather wisdom will be interested in noting that there has been but one May as dry as May, 1887, for the same term of time. May, 1880, was somewhat warmer than last month, and it was likewise a fraction drier. The coincidence is sufficiently striking to invite meteorologists to make search for other synchronous phenomena.

—It is said that there is not a horse doctor who would change places with the average family physician. They make from $3,000 to $5,000 a year, or from $15 to $20 a day, and the anxiety they undergo is not half so great as that of the man who has human patients to attend to. The veterinary surgeons all make money. They charge $2 a visit, though the ailment be nothing more serious than influenza. They often have their own "drug stores," and make a big profit out of them.

—In *Scribner's Magazine* for July, Prof. D. A. Sargent, M. D., of Harvard College, who is perhaps the best authority in this country on the general subject of athletics,

will publish, as the fruit of many years' practical experience, his first extended article in that field, under the title "The Physical Proportions of the Typical Man." In it Professor Sargent will give a standard of physical measurement, based on the measurements of ten thousand individuals. This furnishes a basis of comparison by which any person can gauge his proportions with those of the typical man. The article will contain charts for this purpose, founded on these observations.

OBITUARY NOTICE.

Dr. Albert Kellogg.

Dr. Albert Kellogg, the pioneer botanist of the Pacific coast, and the last surviving charter member of the California Academy of Sciences, died at Alameda, March 31, 1887.

Registrar George E. Chambers.

George E. Chambers, Registrar of the Bureau of Health, died in this city. His illness was caused by an affection of the heart, and lasted over five weeks. Mr. Chambers was about fifty-five years old, and a native of Philadelphia. He began his public life as a clerk in the office of County Controller Hufty. When the Registry Bureau of the Board of Health was established on July 1, 1860, he was elected Registrar, and continued in that office until his death. He took a great interest in his work, and was regarded as a very expert statistician. He leaves a wife and two sons, one of whom is Dr. George H. Chambers, Assistant Demonstrator of Normal Histology in the Medical Department of the University of Pennsylvania.

Dr. William Gardener.

Dr. William Gardener, for many years a practicing physician in this city, died on Wednesday evening, June 1, 1887, of pneumonia, at his residence, southwest corner of Seventh and Parrish streets. He was born in Bristol, England, in September, 1814, and came to this country when twenty years of age, settling in Philadelphia. After serving for a time in the pharmacy of Dr. Emanuel, he studed medicine, and graduated in 1842 from the Pennsylvania Medical College.

Dr. Gardener devoted a portion of his early medical career to practicing his profession along the banks of the Schuylkill river, his journeys being always made on horseback. He took a great interest in medical matters, and, it is said, was one of the founders of the Medico-Chirurgical College. He was also connected with several medical organizations, including the County Medical Society.

Official List of Changes

OF STATIONS AND DUTIES OF OFFICERS.

Medical Department U. S. Army, May 29 to June 4, 1887:

Major B. E. Fryer, surgeon, granted two months' leave on account of sickness; permission to apply for an extension. S. O. 28, Div. Pacific, May 28, 1887.

Captain Paul R. Brown, ass't surgeon, granted leave of absence for four months. S. O. 126, A. G. O., June 2, 1887.

Capt. H. O. Perley, ass't surgeon, relieved from duty at Ft. Maginnis, M. T., and ordered for temporary duty at Fort Snelling, Minn. S. O. 49, Dept. Dakota, May 23, 1887.

1st Lt. Leonard Wood, ass't surgeon, ordered for temporary duty at Fort Huachuca, A. T., relieved from duty at Hdqr's Dept. Ariz. S. O. 126, A. G. O., June 2, 1887.

1st Lieut. Wm. N. Suter, ass't surgeon (recently appointed), ordered for temporary duty at Washington Barracks, D. C. S. O. 122, A. G. O., May 27, 1887.

In the Medical Corps of the Navy for the week ending June 4, 1887.

Surgeon John F. Bransford, ordered to the Smithsonian Institution at Washington, D. C.

Surgeon J. Rufus Tryon, detached from the U. S. S. "Quinnebaug," and ordered home.

Surgeon Charles A. Siegfried, ordered to the U. S. S. "Quinnebaug."

Assistant Surgeon William Martin detached from the U. S. S. "Pinta," and ordered home.

Passed Assistant Surgeon Henry B. Fitts, detached from the Receiving Ship "Vermont," and ordered to the U. S. S. "Pinta."

Assistant Surgeon James G. Field, ordered to the Receiving Ship "Vermont."

U. S. Marine Hospital Service, for the week ended June 4, 1887:

Goldsborough, C. B., surgeon, detailed to represent the service at the meeting of the American Medical Assoiation at Chicago, Illinois, June 6, 1887. June 1, 1887.

Banks, C. E., passed assistant surgeon. When relieved to rejoin station at Boston, Mass. May 23, 1887.

Norman, Seaton, assistant surgeon. When relieved to rejoin station at Cape Charles Quarantine. May 26, 1887.

Press of Inquirer Printing Company, Lancaster, Pa.

WHOLE No. 1581.] JUNE 18, 1887. [VOL. LVI., No. 25.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

SOLUTION FERROUS MALATE.

FOUR GRAINS TO FLUID DRACHM

(Amer. Phar. M'f'g Co.)

DOSE.—30 to 60 drops, four times a day.

Exerts the full therapeutic influence of iron, while it does not constipate, nauseate, produce headache, or cause any of the other unpleasant effects resulting from the use of ordinary forms of iron.

Solution Ferrous Malate will combine perfectly with Acid. Sulph. Aromat. and in this form really represents the therapeutic value of the Tinc. Chloride Iron, rid of all its objectionable features.

The late Prof. Gross, who at one time had occasion to use it in his own case, said, "I am highly pleased with it. I obtained all the benefit from it that I can get from Iron."

Ferrous Malate, Gentian and Cinchona.

(Amer. Phar. M'f'g Co.)

DOSE.—Dessert to table spoonful three times a day.

This is said by Physicians to be a happy combination, embodying as it does, a blood tonic, a stomachic and an anti-malarial, as well as a beneficial conjoint influence that neither Iron, Gentian or Cinchona alone is known to possess.

JOHN C. BAKER & CO., Wholesale Agents,
815 Filbert Street, Philadelphia.

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter. INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant. Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

Lecture.

ON THE TREATMENT OF DROPSIES DUE TO DISEASES OF THE HEART.*

A CLINICAL LECTURE BY PROFESSOR DUJARDIN-BEAUMETZ.

Of Paris, France.

Summary.—*Diuretics — Digitalis — Milk—Mineral Waters — Diuretic Tisanes — Nitrate of Potash — Diuretic Wines and Electuaries — Purgatives—Drastic Purgatives; their Advantages and Disadvantages —Purgative Tinctures, Electuaries and Pills—Sudorifics—Jaborandi and Pilocarpine—Local Treatment of the Dropsies—Œdema of the Inferior Members—Dangers therefrom — Punctures with Needles—Incisions—Drainage Tubes — Croton Oil—Effusions into the Pleural Cavities—Indications for Aspiration in These Cases—Ascites—True Cirrhosis Compared with Cardiac Cirrhosis—Indications for Abdominal Paracentesis.*

Gentlemen: You know that one of the first symptoms of mechanical disturbances effected in the circulation by non-compensated mitral affections, is the presence of serum in the cellular tissue, and in the different closed cavities of the organism. To combat the œdema, and these dropsies, which sometimes take on enormous proportions, the physician has various means at his command. Sometimes he will endeavor to augment the quantity of the urine; sometimes, addressing himself to the digestive tube, he will try to remove by this channel the liquid accumulated in the cellular tissue; sometimes, finally, he will utilize the eliminative function of the skin by stimulating the perspiratory glands.

To each of these therapeutic indications corresponds a group of special medicaments; diuretics, purgatives, and sudorifics. We shall study these successively. Let us begin with the diuretics. I shall not here take up the study of the physiological action of this group of medicaments: I shall state my views on this point when I come to speak of the kidney from a therapeutic standpoint, and I shall then show you how we may subdivide the different diuretic agents. These, as you will see, may all be grouped in four great classes.

In the first class are included those medicaments which cause diuresis by augmenting the blood pressure, which they effect by energizing the heart's action, or by acting on the muscular elements of the circulatory system. The second class comprehends medicaments which augment the quantity of the urine by increasing the blood pressure, and by modifying the blood itself. To the third class belong medicaments described under the name *dialyzers, i. e.* which modify the blood by introducing saline elements. The fourth class is constituted by medicaments which act by irritating the glandular elements of the kidneys. I cannot here enumerate all the medicaments which enter into these different groups. To the first belong digitalis, caffeine, convallaria, ergot of rye, etc.: to the second, water and most of the diuretic infusions, as well as the greater part of the mineral waters regarded as diuretic, and which act much more by the quantity of

*From advance sheets.

water which they represent, than by the saline substances which they contain; in this group we should place milk and wine, particularly white wine. The third group comprehends the dialyzing saline substances—nitrate of potassium, acetate of potassium, nitrate of sodium, etc. In the fourth group, whose very existence is still contested, and which act by congesting the kidneys, we should place certain resins and balsams.

In dropsies due to disease of the heart, the physician should endeavor to utilize all these diuretic groups, and I will now give you some precise indications as to the medicaments most useful in the treatment of cardiac œdema.

We shall give the foremost place to

DIGITALIS.

I showed you in the foregoing lecture the good effects of this tonic of the heart, and I can only add to what I then said by setting forth its no less great utility as a diuretic agent.

It is here that the infusion of digitalis gives the best results. Suppose, for instance, that you have to treat one of those bad cases of heart disease in which the face is puffed, the limbs swollen, with general œdema and dropsy; the patient is suffering from dyspnœa and labors so for breath that you fear that asphyxia is imminent; give this patient the infusion of digitalis, and you will witness a marvellous restoration—diuresis will become more abundant, and in a few days' time the anasarca and the effusion in the serous cavities will have disappeared.

You can hardly expect to witness such effects from digitaline, which, as before said, is uncertain as a diuretic.

To prepare the infusion, you will follow the rules laid down in the last lecture. As for the mode of administration, this differs according to different authorities. Some give progressively increasing doses; others continue the dose with which they began; others give the infusion in decreasing doses. The first method is a bad one; the cumulative effects of the medicine tend very rapidly to intolerance. The method of stationary doses enables one, it is true, to prolong the administration of the medicine, but it will be necessary to give very moderate doses, not more, in fact, than thirty centigrammes (gr. v.) a day of the powdered leaves; this is Herard's plan. The method of decreasing doses is an excellent way; you thus obtain an immediate effect, sufficiently powerful, without intolerance.

Then come

CONVALLARIA AND CAFFEINE.

If you employ the first, you may give the extract in the dose of from 1 to 2 grammes (15–20 grs.) a day. When you prescribe caffeine, do not forget to order large doses, and do not scruple to give from 1 to 2 grammes (15–20 grs.) a day; and if administration by mouth is impossible, practice the subcutaneous injections of benzoate of caffeine and of soda. When you give caffeine by the mouth, you can make use of the pure caffeine, as Huchard does, or the bromhydrate or citrate of caffeine, according to Gubler's recommendation; or, better still, of the solution of caffeine and benzoate of soda, according to the formula which I gave you in the last lecture:

℞. Benzoate of soda,
Citrate of caffeine, āā ℈iv.
Water, f. ℥ij.
M. Sig.—A teaspoonful t. i. d.

In the case of children, you can follow the custom of Jules Simon, and combine squills with digitalis. My colleague of the Hôpital des Enfants, often makes use of the tincture of squills, which he gives in the dose of 5 to 10 drops every three hours.

By the side of digitalis and its infusion I would place milk as one of the best diuretics. The value of a milk diet in the treatment of dropsies has long been recognized. Christian, of Montpellier, Serres, of Alais, Guinier, and especially Pechollier, of Montpellier have shown the advantages of the free administration of milk in cardiac affections, and more recently Potassi has confirmed the conclusions of these clinical observers. I need not here dwell upon the rules for the administration of this dietetic remedy, which consist in allowing only milk at stated periods, and foods prepared with milk. I shall give more complete directions on this point when I come to speak of affections of the stomach and of the kidneys. The milk should not be boiled, and its diuretic properties are enhanced by the addition of alkaline waters, such as Vichy, in the dose of a tumblerful to the quart. Milk has here a double therapeutic action; it is not only diuretic, but it tends to combat (as I shall show you) one of the most constant phenomena pertaining to the congestion of the kidney, the albuminuria.

Digitalis, extract of convallaria, and caffeine, on the one hand, milk on the other—these are the principal remedial agents to which you should have recourse. You may add cream of tartar, nitrate of potash, with whose diuretic properties you are acquainted, and, especially, acetate of potash, the happy

effects of which Marotte has shown. These salts are generally given with some diuretic infusion, as broom-top or couch-grass. But do not forget that if nitrate of potash has diuretic properties which are incontestable, it has also the property of irritating the digestive tube, of provoking diarrhœa and even vomiting, hence you ought in due time to suspend the medicine, or to diminish the dose, and never exceed thirty to sixty grains of the salt to each quart of the infusion. I know well that practitioners have given more, but I believe such administration to be without advantage to the patient, without marked action on the quantity of urine excreted, and to be hurtful to the digestive tube.

(*To be continued.*)

COMMUNICATIONS.

EIGHTEEN CASES OF EXTERNAL PERINEAL URETHROTOMY.*

BY H. C. WALKER, M. D.,

Professor of Genito-Urinary Diseases and Clinical Surgery in the Detroit College of Medicine.

The report of the following cases implies somewhat more than the title of my paper would indicate, namely, external perineal urethrotomy; for in all the cases I had necessarily to make internal urethrotomy of the pendulous urethra.

Case 1. H. C., aged 38. Had gonorrhœa in 1865, lasting several months, ending in gleet. One Sunday, in 1867, after a long ride on a velocipede, he discovered that he could not urinate, and he did not pass any urine until the following Wednesday morning. After treatment with instruments for some time without success, his physician attempted to destroy the constriction with stick nitrate of silver, which unfortunately slipped from its holder and remained in the urethra, causing extensive inflammation, which compelled him to keep his bed for several weeks. In 1869 he was again attacked with retention of urine, which was relieved by the passage of small-sized bougies, gradually dilating to the size of a No. 8 (English). He continued the use of instruments with varying success until March, 1882, when I saw him, and at that time I could pass only a filiform bougie. I informed him of the necessity for an operation; but, owing to business engagements, it was not convenient for him to remain. I did not see him again until June 13, 1884, when he sent for me and informed me that he had been confined to the house and his bed for several months with a number of attacks of swelled testicle and cystitis, accompanied with chills and a frequent desire to urinate. On August 11, 1884, he came to Detroit and entered Harper Hospital, and on Wednesday, August 13, I operated upon him. Examination revealed: Size of meatus 10 mm., at one inch 8 mm., and at 5½ inches a filiform bougie was hugged tightly, showing that the urethra was constricted nearly its entire length. Passing with difficulty a No. 2 (English) tunneled sound (Gouley's) over a filiform bougie, I proceeded by making a free incision 2½ inches in length, extending from the scrotum to within a half inch of the anus and down upon the tunneled sound, completing the incision with a probe-pointed knife, through a dense cicatrized urethra as far as the prostate body, at the same time dilating the prostatic urethra so far as to admit of exploration of the bladder with my finger. I then proceeded to dilate the anterior urethra with a Thompson's divulsor sufficiently to admit an Otis's urethrotome, which was passed through the urethra and out of the opening made in the perineum. I then dilated and cut to admit a No. 33 sound through the whole length of the urethra into the bladder.

I had previously examined several specimens of the patient's urine, and had found large quantities of pus-cells and epithelium from the bladder, urethra, and prostate gland, but no casts. The specific gravity was about 1020, and the reaction unusually alkaline. For several days before the operation he had taken quinia, iron, and bromide of potassium. This was continued after the operation, with the addition of tincture of aconite in drop doses every hour, and the application of an ice-bag to the penis and scrotum. August 14: Has had a comfortable night; temperature 99.2°; pulse 84; urine passed through the perineal opening. August 15: Slept well; holding urine from three to five hours, and has passed it mostly through the urethra. August 16: Had a severe chill, followed by rise of temperature to 102½°; pulse 110. Urine passed wholly through the urethra. Previous treatment continued. August 17: Has had no chill since: temperature normal; continued treatment. August 18: Passed No. 26 (French) sound with little pain and slight hemorrhage. August 20: Passed No. 26 with ease. Patient got up to-day, and is doing well. Remedies discontinued, and full diet ordered. Patient holds his urine from five to eight

*Read before the Section on Anatomy and Surgery of the American Medical Association, at Chicago, June 8, 1887.

hours. September 11: Have been passing No. 28 at intervals of every two days, The perineal opening has entirely healed, and the patient himself passed a No. 15 (English), which I instructed him to continue doing at intervals of every three or four days.

I saw this patient last winter. and passed a No. 14 (English) with ease. He informed me that he has no inconvenience further than the passing of the instruments at intervals of every three or four days since the operation.

Case 2. J. C., aged 52. Had gonorrhœa at the age of 18 years, and several times since. I saw him first in 1876, when he was suffering from retention of urine. Succeeded in passing a No. 2 gum bougie, and treated the patient by gradual dilatation until a No. 8 could be introduced. He left me, and I did not see him again until January, 1881, when I faithfully attempted to dissolve the strictures by electrolysis, without any benefit. This method of treating strictures I have tried in a number of cases, and have never been able to attain anything further than what might be attained by ordinary dilatation.

The patient would not submit to an operation, but left me, and I did not see him again until August 15, 1884. He then sent for me, and I found that he had been confined more or less to his bed for several months, suffering from abscesses in the perineum, swelled testicle, cystitis, and great frequency in urination. The most of his urine passed through the several fistulæ. He was now ready for the operation which I had proposed. His general condition was bad, with an evening temperature of about 101°; urine alkaline, containing large quantities of pus and of bladder epithelium, but no evidence of kidney trouble.

After a few days' preparatory treatment, the operation was made on August 20th, 1884. In this case I was compelled to operate without a guide, for, after prolonged and persistent effort, I failed to introduce a filiform bougie further than four inches; and in order to facilitate the introduction over it of a tunneled sound, down to the point of obstruction, I cut the meatus with a meatotome, such as I exhibit made for me by Tiemann & Co. (Fig. 1.)

You observe that it has a rectangular cutting edge, with a probe point at the upper border. It does the work much easier than any other knife which I have used for this purpose.

The operation was completed with difficulty, and considerable loss of blood, which was controlled by torsion of two or three small vessels. The urethrometer distended to 35 (French) was then passed through the entire urethra into the blader. For about a week the patient did well, with only a slight rise of temperature on the fourth day, following the introduction of a No. 28 steel sound. August 28 he had a severe chill, with considerable tenderness above the symphysis pubis. September 5, I opened an abscess, just below the umbilicus, which discharged freely for several days. September 20, the opening in the perineum had healed, and a No. 26 sound could be easily passed. I saw the patient a few days ago, when he informed me that he had no further trouble, and that he passed a No. 12 (English) sound occasionally. He stated, however, that he had lost all sexual desire since the operation.

Fig. 1.

Case 3. W. M., aged 42, intemperate, a victim of many gonorrheas, dating back for a period of twenty years. First came under my observation November 1, 1884, through the solicitation of his physician, Dr. S. G. Miner. At that time he was suffering from multiple abscesses in the perineum and left inguinal region, through which the urine percolated. The abscesses were discharging profusely, and the patient was in a pretty forlorn condition. I saw him again on January 8th, 1885, when he was somewhat improved in general health. Several fistulæ still existed. With much difficulty a filiform bougie was passed, and over this a No. 2 tunneled sound. Upon this the perineal cut was made, and the incision of the pendulous urethra was completed with Otis's urethrotome, so as admit the urethrometer distended to 35mm. throughout its entire length. The fistulous tracts were then laid open and the prostatic urethra distended.

The after treatment consisted in giving liberal doses of quinia, and applying a bag of pounded ice to the parts. January 9th. The patient had vomited considerably during the night, and had several severe chills. At 10 a. m. his temperature was 106°, pulse 120. I did not see this patient afterwards, but the following is the history of the case as furnished me by Dr. Miner:

January 10: Somewhat better; temperature 104°; pulse 120; was delirious during the night. January 15: Has been improving gradually, and is able to sit up. Passed

easily a No. 16 English sound. February 1: Wound in perineum healed; have no difficulty in passing a No. 16 sound. July 1: Has gained materially in weight; passing the sound at intervals of every two or three weeks.

The doctor informs me at the present writing that his patient is well, and passes a full-sized sound with ease.

Case 4. D. C., aged 52. First saw him November 28th, 1884, at Battle Creek, Michigan, with his physician, Dr. S. S. French. Had a history of stricture for over ten years. The meatus measured 12 mm.; the urethra gradually diminished in size; at four and a half inches it measured 1½ mm. I did the operation as in the preceding cases, passing a No. 28 (French) steel sound. The patient did fairly well, and in the summer of 1885 went to California, remaining for several months, at the same time neglecting to pass an instrument. On his return to Battle Creek his old symptoms returned, namely, frequency in urinating, cystitis, and chills and fever at any attempt to introduce an instrument. He sent for me, and I operated on June 5, 1886, making the second perineal section. His recovery was tedious, and Dr. French informs me that on erection there is curvature of the penis at its under surface about an inch back from the meatus. The second operation could have been prevented had he kept up the dilatation as directed.

Case 5. G. McC., aged 47. First came under my care April 15, 1885. At that time he was suffering from a large perineal abscess, which I opened. He informed me that he first contracted gonorrhœa at the age of twenty years, and syphilis in 1874. Partial paraplegia (undoubtedly syphilitic) showed itself about 1879, and at the same time he had difficulty in voiding urine, although some time before this he had been treated for stricture by gradual dilatation, with benefit. On examination I found that the meatus measured 18 mm., and in the deep urethra a 1½ mm. filiform bougie was grasped tightly.

May 28, 1885, after preparatory treatment, I made perineal section and cut the entire urethra to the extent of 32 mm., and laid open the fistula. The patient recovered rapidly, and without an untoward symptom. He gained in flesh, and rides to and from his business daily, with greater ease than at any time since the attack of paraplegia. He keeps his urethra open by passing a No. 15 (English) steel sound at short intervals.

Case 6. T. L., aged 56; contracted gonorrhœa during the war; was operated upon by internal urethrotomy in 1878. He entered Harper Hospital, July 6, 1885, with the following symptoms, which had existed for more than a year. Frequent urination, especially during the day, and exasperated by rapid walking or riding; cystitis, as shown by the large quantities of bladder epithelium which were discovered with the microscope. It was with great difficulty that the smallest filiform bougie could be introduced. I operated July 10, 1885, and on exploring the bladder found a phosphatic stone weighing 185 grains.

This patient made a quick recovery, leaving the hospital on the tenth day. I have heard from him since, and he informs me that he has had no further trouble, and that he passes a No. 12 (English) with religious regularity.

Case 5. H. Y., lumberman, aged 45. Came to me July 16, 1885, for relief of a perineal fistula, following an external perineal urethrotomy, made three years before by a surgeon of New York. At the time of his visit to me he had passed no urine through the pendulous portion of the urethra for several months. I made repeated attempts to pass the smallest filiform bougie, but failed.

Operation July 23, 1885. I first made a free incision through a dense cicatricial mass in the perineum, and after prolonged effort succeeded in finding my way into the bladder. I then introduced Syme's staff through the meatus, but it was arrested at a distance of three inches. It was held in position, and I gradually cut the way up from the cut below to the point of the staff, and then dilated thoroughly and cut with an Otis's urethrotome, so as to pass a steel sound No. 16, through the entire length of the urethra, and into the bladder. The patient left for his home on the thirteenth day, with the fistula in a fair way to heal, with positive instructions to keep up the dilatation. I have not heard from him since.

Case 8. J. R., aged 35. Presented himself to me in May of 1885, with a well defined history of stricture. He had had gonorrhœa several times, the first attack dating back fifteen years; also had syphilis in 1875. I tried several times to pass a filiform bougie, but failed. There existed in the perineum a dense cicatricial mass, the result of an old perineal abscess, through which some urine passed for a time, but which closed up spontaneously. He complained of severe pain following each micturition, and often had attacks of retention. As gradual dilatation

did not accomplish anything, he gave his consent to an operation, which I made July 27, 1885. After the patient was etherized, I succeeded with but little effort in introducing the filiform attachment of a urethrotomy staff which I devised (Fig. 2).

I deem the gradual stretching of the prostatic urethra a procedure of importance, not only for the purpose of exploring the bladder, but also because by temporarily paralyzing that portion of the urethra, it aids materially in relieving any cystitis that may

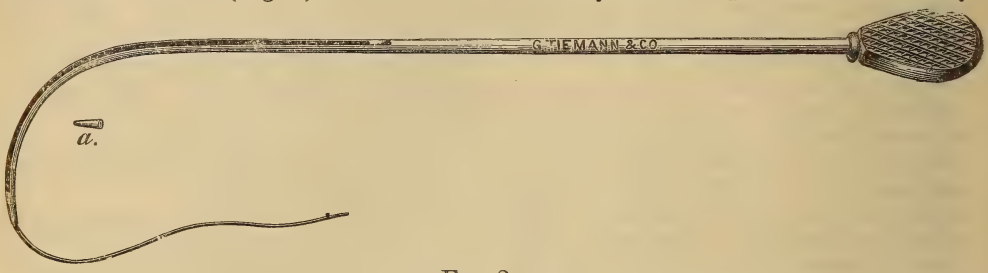

Fig. 2.

Fig. 3.

The staff was pushed forward, and cut down upon in the perineum, and the section was completed with a triangular probe-pointed knife, which I had made for me by Tiemann & Co. (Fig. 3.)

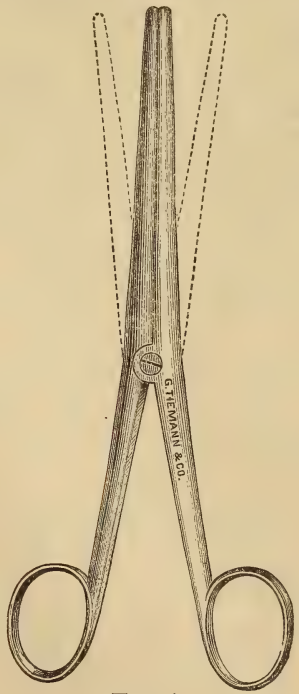

Fig. 4.

I then gradually dilated the prostatic urethra with the prostatic dilator, an instrument which I devised for this purpose. (Fig. 4.)

and usually does exist in cases of long-standing stricture of the deep urethra.

In this case I discovered a phosphatic stone, weighing 110 grains, which I crushed and removed with an evacuator. With the exception of œdema of both feet for a week or two, the patient made a rapid recovery. I saw him a few days ago, and he reported himself in excellent health.

Case 9. R. S., aged 51. First consulted me in October, 1885, presenting the usual symptoms of long-standing stricture. Gave a previous history of several gonorrhœas, and on examination I discovered a number of strictures in the pendulous urethra, and a tight one of considerable length in the deep urethra. Tried gradual dilatation for some time, without any benefit. Made the operation November 19, 1885, cutting the urethra to the extent of 36 mm.

The recovery in this case was good, the temperature rising to 103° for a few hours on the third day after the passage of a sound. He has had no trouble since the operation, and comes to the office at intervals of every two or three weeks to have the sound introduced.

Case 10. E. F., aged 27. Entered Harper Hospital November 15, 1885, for the relief of several urethral fistulæ. He stated that he had had gonorrhœa ten years before, followed by two other attacks. Five years ago he had retention of urine. Two years later his perineum, scrotum, and penis began to swell, evidently from retention and extravasation of urine, followed by extensive sloughing of the parts. At the time of his en-

trance to the hospital he was a pitiable object, as at every act of micturition urine flowed from fistulæ in the perineum, the scrotum, and the groin. I was unable to introduce the smallest filiform bougie, either through the fistulæ or through the urethra. December 1, 1885, I laid open and scraped all the fistulæ, and by patient endeavor succeeded in making my way into the bladder, but was unable to introduce anything through the pendulous urethra, except for about one inch back from the meatus.

The patient rallied satisfactorily from the operation, and left for his home in about two weeks. On January 9th, 1886, he returned to the hospital, and I attempted to restore the anterior urethra. But its character had been so destroyed by the sloughing that I did not succeed. His general health was excellent, and all bladder symptoms subsided, with the exception of the inconvenience of urinating through the perineum.

January 23d, 1886, he returned to his home, with instructions to introduce a sound through the opening.

Case 11. Wm. B., aged 58, gives the following history: In 1863 he had an attack of gonorrhœa, which lasted until the summer of 1864, when his horse fell upon him (he being at that time in the cavalry service of the U. S. army) injuring him in the region of the chest, kidneys, bladder and perineum. For two days he was unable to void his urine, and for several days afterwards he passed blood from the urethra and bowels. He was confined to bed at this time for three months, the chest injuries being considered the most serious. The urination continued to grow worse, with occasional retention for several hours at a time. He informed me that in 1876 internal urethrotomy was made with considerable benefit for a time.

When he entered Harper Hospital, January 2d, 1886, he was voiding urine every few minutes. His urine had a specific gravity of 1019, it was alkaline and contained pus and epithelium from the bladder. The urethra measured 10mm. at the meatus, and 2mm. at 2½ inches; the remainder hugged a filiform bougie tightly.

January 16, 1886, I made the operation, by first passing Maisonneuve's instrument with the smallest filiform attachment, and then pushing the large knife the whole length of the groove, cutting the floor of the urethra so as to admit a lithotomy staff. When this can be done it simplifies the operation, and is preferable to passing a filiform bougie, and then over it Gouley's tunneled sound, as the completion of the cut in the perineum is interfered with by the bougie in the groove of the instrument. The operation was completed as in previous cases, admitting a 36mm. steel sound.

This case made a good recovery without an unpleasant symptom, and he left the hospital with directions to keep up passing a full-sized sound every few days. I saw the patient in January of 1887, and he had some frequency in voiding his urine, although I passed without difficulty a No. 15 (English) steel sound.

Case 12. J. L., aged 24. Came to me through the kindness of Dr. Shurley, of Detroit, January 24, 1886. He had a constant dribbling of urine, so that he was compelled to wear a rubber urinal. Two years before, he fell through a hatchway, striking upon his perineum, and it was several hours before he passed urine, which was mixed with blood, and continued so for several days. A lessening in the size of the stream was observed in a very short time after the injury. He had had several attacks of retention, and for the last six months the urine had dribbled constantly. He admitted having had a gonorrhœa in 1880, which lasted several months. Examination revealed a diminished size of the anterior urethra, and a tight tortuous contraction of the deep urethra. January 27, 1886, the patient was anæsthetized, and a urethrotomy staff, with attachment, introduced. I divided a dense cicatricial mass in the membranous urethra. After a free division of the meatus, I completed the operation with Otis's urethrotome, and introduced a No. 28 (French) sound.

On the evening of the third day the patient had a severe hemorrhage, following an erection, which was finally controlled by introducing a No. 17 (English) steel sound, and allowing it to remain in the urethra. He had no further trouble, and left the hospital on the fourteenth day, with the opening healed. I have seen him several times since, and have passed a No. 15 (English) sound.

Case 13. J. P., aged 27, farmer; entered the Detroit Sanitarium about the first of August, 1886. At the request of Dr. J. Snyder, I saw and examined him. He stated that he had had gonorrhœa in 1879, and had never been free from gleet since, and several times following the sexual act would have a "fresh dose of clap," which generally ceased in a few days. In 1882 he observed an appreciable lessening in the size of his stream. Shortly after this he had retention, and gradually grew worse, having frequent chills, and great distress in urinating. Exploration showed the size of the

urethra to be 12 mm. at the meatus, while at five inches a capillary bougie fitted the constriction tightly.

I advised an operation, and performed it on August 7, 1886, first introducting a whalebone guide, and then over it a tunneled dilating urethrotome (Fig. 5), which I here exhibit to you, which I had made for me by Tiemann & Co.

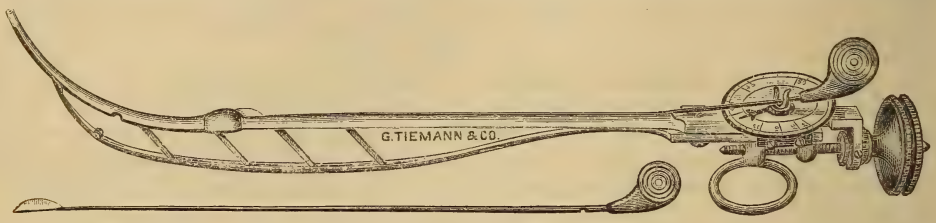

Fig. 5.

The instrument consists of parallel steel bars, the lower being segmented at a point where the curve begins, and held together by bars which can be separated or closed by means of a button-screw at the end. In the upper bar is a groove into which the knife glides, and when not in use is concealed by a small half bulb opposite the commencement of the curve. The distal end of the instrument is tunneled, measuring two millimetres in diameter. By means of this instrument, when a guide has been once introduced, we are able to cut a way through by just pushing the knife forward from its concealment in the bulb, and when it is once passed beyond the point of constriction, the bars are separated by the button screw, dilating the urethra to the extent desired, that to be determined by the indicator, when the knife is drawn from behind forward, and the cicatricial tissue divided. It will be seen that the instrument combines the properties of a tunneled sound, a dilator, and a urethrotome.

After dividing the strictured tissue, a lithotomy staff was introduced and the perineal section made. August 30th a full-sized sound was passed without difficulty, and continued at intervals of every three or four days. The patient left for his home, in Ohio, on September 14th, with the perineal opening closed, and a great improvement in his general health. I have heard from him since, and he reports himself well, and passing the instrument as directed.

Case 14. C. S., aged 53, a book-keeper, came under my care September, 1886, with a history of gonorrhœa when a boy. For the last ten years he has had difficulty in passing urine. Several months ago he had a perineal abscess, which opened spontaneously, and has been discharging pus and urine ever since. He has several strictures, together with chronic cystitis and pyelitis.

I operated on September 27th, 1886, by the same method as in the preceding case, and laid open an extensive pus cavity in the perineal region. My patient did well for three days, when I passed a No. 28 (French) sound, which was followed by a severe chill and high temperature. He remained in a precarious condition for several days, when he improved, and I again introduced the instrument, with the same results as before, since which time I have refrained from introducing an instrument.

His recovery has been tedious, and at the present time he is not entirely well, the chronic cystitis and kidney troubles still existing, and a small fistula, through which a few drops of urine escape at each urination. He is, however, much better than before the operation.

Case 15. C. B. F., aged 45, a commercial traveler, consulted me in August, 1886, with a record of several gonorrhœas, the first dating back to the war, when he was a soldier. For the last eight years he has suffered with a frequent desire to urinate. Examination revealed the size of the urethra to be 10 mm. one-third inch from meatus, and ½ mm. at five inches.

I attempted gradual dilatation for a time, without benefit. Advised perineal section, but he concluded to wait awhile. October 29, 1886, he telegraphed that he was coming on the next train, as he could not pass his water. On his arrival, I sent him to the Detroit Sanitarium, and after persistent effort failed to introduce the smallest instrument. I then aspirated above the symphysis and drew off 47 ounces of ammoniacal urine. Next day he had to be aspirated again. November 1, 1886, I succeeded in introducing a capillary bougie, and performed the operation. The chills and fever that he had every little while before subsided, and he rapidly improved without a bad symptom, and left for home November 21, with instructions to keep the canal open.

Case 16. D. McD., aged 42. Entered St. Mary's Hospital March 7th, 1887, with the following history; Habits intemperate; denies that he ever had gonorrhœa, although he has had difficult urination for several years. About two years ago, after an extended debauch, he noticed a swelling in the perineum, followed by retention and general extravasion of urine in the perineum and scrotum, finally breaking down into a large abscess, which opened spontaneously at several points, through which most of the urine has passed up to this time. March 11th, 1887, the patient was anesthetized. I made prolonged effort to pass a filiform bougie, and failed. I then introduced Syme's staff as far as it would go, which was about four inches, and cut down upon its point, gradually working back until I entered the bladder. The fistulæ were laid open and a No 27 sound passed. He made an excellent recovery, and left for his home in Canada April 1st, 1887.

Case 17. R. G., aged 53, book-keeper. Was first seen by me March 7th, 1887, in consultation with Dr. D. McLeod. He had been suffering with stricture for several years, as the result of a gonorrhœa when a young man. I found him suffering with constant desire to urinate, and with a fistula in the perineum, which had been there for several months. On exploring the urethra, the urethrometer met with resistance. Just within the meatus the instrument expanded to 12mm., and at 4½ inches, it admitted only the smallest sized filiform. On examining the urine I found evidence of chronic cystitis and pyelitis. On March 22d, 1887, after treatment for the purpose of building him up, as he was very much debilitated, I operated, making the usual perineal incision and a thorough division of all the strictures. On the next day the temperature rose to 102°, and never fell below that until his death, which occurred March 28th, 1887. Although no post-mortem examination was permitted, I am of the opinion that he died from pyelonephritis and abscess of the kidney.

Case 18. W. L., aged 45. Entered St. Mary's Hospital May 10th, 1882. Has had two attacks of gonorrhœa, the first over 20 years ago, and the last about three years ago. His first notice of interference with his flow of urine was about twelve years ago, and had several attacks of retention. About five years ago he was operated upon by internal urethrotomy. At the time of his last attack of gonorrhœa, retention occurred and extravasion of urine in the perineum, scrotum and penis, which broke down and opened spontaneously. In his present condition he presented a dense cicatricial mass in the perineum and scrotum, in which there were several fistulæ. He also had a large, dense, redundant prepuce, which would not admit of the introduction of an instrument into the urethra.

May 13, 1887, I operated, first slitting up the prepuce. I failed to introduce a filiform further than 4¼ inches, neither was I able to pass one into the bladder through any of the fistulæ. I then introduced a grooved staff as far as the obstruction, and made the perineal cut, dividing the urethra on the point of the staff. After careful manipulation, I succeeded in introducing a small grooved silver probe, cutting the remainder of the strictures, dilating the prostatic urethra, and explored the bladder with my finger. I then divided the strictures in the pendulous portion, and completed the operation by circumcising the prepuce, laying open the fistulæ, and thoroughly washing out the bladder and urethra with a one to five thousand solution of mercuric bichloride.

On May 16, I introduced a No. 16 (English), and continued to do so at intervals of every three or four days. He is now passing all his urine through the urethra, and will undoubtedly soon be able to leave the hospital.

Of the eighteen cases reported in this paper, one was operated upon twice, making nineteen operations in all. One died within a week following the operation; death due to to renal disease. Fifteen were relieved entirely of all symptoms, and the remaining two were much improved, although some distress in urination still remains. In all cases there is a tendency to re-contraction of the urethra, certainly not from a want of thorough division of cicatricial tissue, as this was done in each case with the greatest care, following out faithfully afterwards the introduction of full-sized steel sounds at stated intervals.

In conclusion, I would say that the accepted methods of treating strictures are by dilatation and by incision, although various other methods have been tried with variable success. Dilatation stands preëminent as a means of treating strictures in the large majority of cases, yet it cannot be denied that the cutting of strictures of large calibre has proved beneficial in many instances and relieved many reflex troubles which would not succumb to dilatation. This is specially true of all strictures at or near the meatus. Although there is much weight of testimony

in favor of the radical cure of stricture by incision, I am not prepared as yet to accept the statement, for I have cut many strictures, dating back for a period of twenty years, and I do not know of any which will not close up if not kept open by occasional introduction of a sound. Old and tight strictures, which will not succumb to dilatation, are best treated by incision, those of the deep or fixed urethra, by a combination of external and internal incision, and those of the pendulous urethra by internal urethrotomy.

FOUR CASES IN WHICH RETINAL HYPERÆSTHESIA WAS ASSOCIATED WITH OXALURIA.

BY G. E. DE SCHWEINITZ, M. D.,
Ophthalmologist to the Orthopœdic Hospital and Infirmary for Nervous Diseases, Ophthalmologist to the Philadelphia Hospital.

The following four cases illustrate a point in therapeutics which renders their brief record not unworthy:

Case 1. E. D., aged 16, a freshman in college. The patient was six feet three inches in height, and was over six feet when thirteen years of age. He was despondent, easily tired, and subject to stubborn winter cough, though no pulmonary or cardiac lesions were detected. He experienced some heaviness after eating, and had occasional attacks of diarrhœa of a lienteric type. The knee-jerks were normal. The urine, on the statement of his family physician, contained no abnormal ingredients. The ocular symptoms were: a constant pain in the eyes, and frontal headache, aggravated by all near work. Dread of light, and occasionally diplopia, were added to the symptoms just detailed. Examination of the eyes revealed the following points:

R. E. $\frac{15}{XX}$ Jaeger No. 1 5–10.5 inches.

L. E. $\frac{15}{XXV}$ Jaeger No. 1 5–13 inches.

Slight insufficiency of the internal recti.

In the right eye the nerve was irregular, the retina striated, the lymph sheaths along arteries and veins distended; apparently a low hypermetropia existed. In the left eye a similar state of affairs obtained.

After the use of a mydriatic (homatropine) the refractive error was found to be

R. E. + .60^{s}.

L. E. — .50°, axis 15.

This glass was ordered and the patient put upon tonics, iron, quinine, and phosphoric acid, at different times. Some improvement took place, but the old symptoms constantly recurred, and comfort was not obtained. Finally, a sea voyage was undertaken, and during its continuance and for some time after his return, the young man was quite comfortable. On returning to his studies, however, all his former uncomfortable sensations returned even more decidedly than before. The eyes were then thoroughly re-examined, the glasses found to be accurate, and his physical state systematically overhauled. Repeated examinations of the urine revealed that it was free from albumen and casts, but the sediment was rich in *oxalate of lime crystals*. A solution of the case was at hand. He was put upon nitro-muriatic acid and compound tincture of gentian, with proper regulation of his diet. In a few weeks a surprising improvement took place, and to-day, many months after his original visit, he is a well man, his general as well as his ocular disabilities having disappeared.

Case 2. G. H. J., aged 20, had just completed a college course, and was undertaking the study of law. He was tall, anæmic, and easily fatigued and readily depressed. No cardiac or pulmonary symptoms were noted. With the exception of an occasional feeling of heaviness after eating, no dyspeptic manifestations were present. He complained of pain in the eyes, marked dread of light, and inability to read for any length of time. Examination of the eyes revealed the following conditions:

R. E. $\frac{15}{XX}$ Jaeger No. 1, 13–23 cm.

L. E. $\frac{15}{XV}$ Jaeger No. 1, 11–31 cm.

Insufficiency of the interni 11°.

The ophthalmoscope demonstrated oval optic discs, marked white striation of the retinas and distended lymph sheaths. The refractive error was apparently a low hypermetropic astigmatism. After the prolonged use of atropia, the correcting glass was found to be:

R. E. + .60^{s}⊖.25°, axis 120°.

L. E. + .25^{s}.

The urine had a specific gravity of 1022, was free from albumen, the sediment consisted largely of *oxalate of lime* crystals. Wearing the correcting-glass, the use of tonics, and laying aside of prolonged eye-work gave some relief, but comfort did not ensue until the condition indicated by the urine was corrected.

Case 3. R. H., æt. 19, a senior in college. He dated his troubles to an attack of measles two years ago. He complained of watery eyes, dread of light, pain and inability to read at all by artificial light. He was a short, thick-set man, of good physique, but

very taciturn and distinctly morose. No positive dyspeptic symptoms were elicited; heart and lungs were normal. The eye examination resulted as follows:

R. E. $\frac{15}{XXX}$ Jaeger No. 1, 11–39 ctm.

L. E. $\frac{15}{XX}$ Jaeger No. 1, 12–32 ctm.

Insufficiency of the internal recti 10°.

With the ophthalmoscope it was noted that the optic nerves were physiologically cupped, beginning conus each eye; general gray haze of the retinas and much grayish white tissue along the veins; while the eyes were markedly sensitive to light. After the use of atropine, the vision steadily rose until it became $\frac{15}{XV}$, or normal in each eye, owing to the relief of the spasm of accommodation. A careful examination with the stenopaic slit revealed

O. D.—0.25^c axis H $\frac{15}{XII}$

O. S.—0.25^c axis 15° $\frac{15}{XII}$

as the only existing error of refraction.

He was consequently ordered a weak convex combination and 2° prisms bases in for reading. Examination of the urine revealed that it was acid, contained numerous *oxalate of lime crystals*, but was free from albumen. Regulation of the diet, exercise, and the use of acid. nitromuriat. and gentian produced in this case as in the others marked amelioration of the symptoms, and when last seen he was pursuing his studies with comparative comfort.

Case 4. A. H., aged 23, a student. He was very tall, with non-correspondence between his height and general physical build. No cardiac or pulmonary lesions, although subject to bronchitis. There were distinct evidences of dyspepsia, weight in the stomach, furred tongue, bitter taste in mouth, and irregular bowels. The ocular symptoms were a constant burning pain in eyes, recurring attacks of blepharitis, and dread of light. The chief mental characteristic seemed to be lack of will power. The following is the examination of the eyes:

R. E. $\frac{15}{XV}$ Jaeger No. 1, p. r. 15 cm.

L. E. $\frac{15}{XV}$ Jaeger No. 1, p. r. 15 cm.

Insufficiency, 7°.

The ophthalmoscope revealed round optic discs, prominent vessels, and many of the veins tortuous, fine striation of the retina. He had worn for some time a correcting glass, but did not experience relief of his ocular trouble, the recurring attacks of blepharitis and dread of light being still persistent. The mydriatic was used, and the correction found to be accurate. An examination of the urine revealed that it was acid in reaction, free from albumen, and freely deposited *oxalate of lime crystals*. The usual treatment of nitro-muriatic acid and compound tincture of gentian was productive of most happy results, inasmuch as his dyspepsia and ocular troubles both improved.

Remarks: I am quite aware that to the presence of oxalate of lime in the urine a host of ills, even insanity itself, has been attributed, and that such connection has often had no foundation upon sound reasoning. At the same time I am equally well-assured that, to quote from Dr. H. C. Wood: "There is a morbid condition probably dependent upon defective primary assimilation, in which the chief symptoms are general malaise, a feeling of weakness, a lack of elasticity, a very great depression of spirits, in which crystals of oxalate of lime are generally to be found in the urine, and in which nitro-muriatic acid produces in a few days a surprising revolution." To these symptoms I might add, if it is fair to judge from four cases, *retinal hyperœsthesia*, as indicated by dread of light and irritable and uncomfortable eyes; a retinal hyperæsthesia, moreover, which the prolonged use of a mydriatic, the wearing of a correcting glass, and even abstinence from active eye-work, did not relieve until the existing oxaluria was banished. Whether the ocular symptoms would have subsided under the use of the constitutional measures alone without the aid of the correction of the refraction error I am unable to say. I am of the opinion that they would not have done so, because it is in just such individuals that these slight errors are often productive of mischief, especially if associated, as they were in three of these cases, with insufficiency of the internal recti muscles. I once observed a case of stubborn and unexplained paresis of accommodation in a young woman, which entirely resisted the ordinary methods of treatment, but which disappeared after a thorough urinary analysis revealed the presence of oxaluria, and this was corrected by the administration of nitro-muriatic acid. I am not sure enough of the conection between these two conditions to state it as a positive observation. These cases illustrate quite forcibly another point, always well recognized but too often neglected, viz: the value of systematic examination of the urine; an examination, moreover, which should be made by the physician in charge, and not trusted to what may have been done at some past time in the history of the patient. They emphasize further the important fact that

while special lines of practice and treatment are necessary, the member or organ under treatment should be regarded not as something separate, but only in the light of having vital connections with all the other members and organs, which together form the entire economy. It is often needful to exercise special training, to be in short a specialist in treating disease; but such training is for naught if the owner is not first of all a common-sense physician.

1330 *Spruce St., Philadelphia.*

Society Reports.

THE SIXTEENTH CONGRESS OF GERMAN SURGEONS.

Prof. Madelung (of Rostock), speaking on

Acute Intestinal Obstruction,

insists upon washing out the stomach before giving anæsthetics. (Prof. Kussmaul has shown that this will sometimes induce peristaltic action strong enough to overcome the obstruction.) Then the incision should be made over the tumor, if such is discernible by palpation. If not, the *linea alba* should be incised. In cases where the patient is collapsed, an artificial anus is to be made, and the radical operation is to be deferred till the patient is in better condition. The incision should be long enough to allow sufficient inspection; but under no circumstances should the intestines be drawn out to find the obstruction, because reposition is often next to impossible. Madelung always draws out a small coil of intestine, around which he puts two ligatures; then the patient is turned on his side, and the intestine is cut open and emptied of its contents, while the ligatures are slowly tightened. The incision being completely united again, the gut is returned into the abdominal cavity, and then there will be a much better chance to locate the exact seat of the difficulty. Now the surgeon has to decide whether an artificial anus is to be established or resection can be performed immediately. Peritonitis ought not be considered a contra-indication. Still, laparotomy in such cases will always be successful in a minority of cases only.

Dr. Rydygier (of Kulm) thinks that the operation should be performed as early as possible, and that washing out the stomach should not be undertaken, since it tends to deceive patient and surgeon by a temporary improvement while inflammation continues. The difficulty most frequently is that the seat of the obstruction cannot be exactly located, and therefore laparotomy is deferred too long and is unjustly blamed for the fatal issue if the patient dies. Rydygier has operated seven times and saved two patients. He thinks Czerny is too cautious in demanding that laparotomy should only be performed if the patient is in good condition, if the abdomen is not distended, and if the probable seat of the obstruction can be made out under chloroform. Czerny prefers enterostomy, but Rydygier contends that bands, and adhesions generally, will continue to exert pressure in many cases and cause death by inflammation in spite of the evacuations of feces through the artificial anus. The same is true of volvulus and fecal accumulation. The difficulty of replacing the portions of the gut drawn out is sometimes great enough to cause the operator to shrink from performing laparotomy. Still he has been able to replace the intestine in all his cases. He prefers to make his incision in the *linea alba.* The formation of an artificial anus is indicated only in patients who are already collapsed, and it is doubtful if it will save them then and there. Rydygier therefore implores the practicing physicians to send for the surgeon early, and not lose valuable time with the stomach-pump.

Prof. Credé (of Leipsic) speaks strongly in favor of operating early, although he appreciates the difficulty to induce patients (and physicians) to call in the surgeon at once. His experience, in 30 cases of laparotomy for intestinal obstruction, has led him to believe that it is mostly due to former disease, old adhesions with peritonitis following, or retention of a rupture in which adhesions have been existing for some time, etc. He therefore is anxious to operate when the colicky pains are at their height, and reports three cases in which he was fortunate enough to operate just at that point of time. In one case the cause of the obstruction was found to be an old hernial sac which had not protruded for ten years, when patient had had typhoid fever. The woman frequently had attacks of colic for many hours, but got well spontaneously until the last time. In the hernia the omentum was found to be coiled up in a lump, together with a portion of intestine; besides this, four coils of intestine were matted together by thick adhesive strings (Schwarten), so that it was extremely difficult to disengage them. After operating there remained two fistulæ, which closed afterwards; now the patient is entirely

well and able to do hard (farmer's) work. The other two cases were similarly due to old peritonitic adhesions. Both got well.

Credé states that such conditions of recurrent attacks of colic are more frequent than is generally supposed. Physicians should be aware of this, and advise an early operation; because these are the cases which collapse very quickly when an impassable obstruction is once formed.

Prof. Mikulicz (of Koenigsberg) is much more conservative in his views than formerly. He thinks that laparotomy should be performed only when a mechanical obstruction is recognized beyond doubt. In doubtful cases it should be deferred until signs of collapse supervene. He has on record three cases which were sent to him for operation, about which he hesitated until all three recovered spontaneously. His treatment of largely distended coils of intestine consists in cutting off a portion of the protruding gut, and introducing a tube the size of a finger, and stuffing around it with iodoform gauze. Then the contents are squeezed through the tube into a vessel, and thus the peritoneal cavity is kept clean. The great difficulty is, whether in a given case *peritonitis* is to be considered the prime cause of the condition, or whether it is an after-effect of the abnormal anatomical relations established. At all events, it is a sad fact that the cause of death is, as a rule, *septic peritonitis*. To investigate the course of this dread disease under varying conditions, Mikulicz has made numerous experiments on animals, and these have convinced him that the best results will be obtained by irrigations with salicylic acid solutions, after cleaning the peritoneal cavity thoroughly from all exudations with dry gauze, by leaving the wound partially open, and by inserting drains where needed,

Dr. Schede (of Hamburg) believes the main difficulty to be to make a correct diagnosis. He contends that by washing out the stomach, or even by rest and opium alone, at least 50 per cent. of all the cases get well.* He remembers cases where on the twentieth and even on the thirty-fifth day spontaneous cure took place. Therefore early interference should be restricted to those rapid cases in which collapse begins after a few hours, and then laparotomy is not always advisable. An artificial anus may suffice to tide the patient over the worst stage. Schede has saved only 7 out of 26 cases operated upon, and these were operated upon very early. No cases were due to carcinoma, and he believes this to be frequently the real cause of intestinal obstruction. He thinks that some of these if closely watched may be found to be suitable for operation since the obstructing tumor may be very small. In three cases he found this to be the case, the real stenotic carcinoma involving not more than 2 cm. (1 in.) of the gut.

Prof. Schoenborn (of Würzburg) advocates enterostomy as a primary operation, but points to those cases reported by the late Prof. Frerichs, in which death occurred after spontaneous cures, and where no obstruction but also no cause of death could be found. This may also happen after enterostomy and thorough evacuation.

Dr. Steltzner (of Dresden) prefers early operation to temporizing. He saved 4 cases out of 8, and always opened the peritoneal cavity thoroughly. Of 4 cases of perforating peritonitis, only one got well after laparotomy. The great difficulty of replacing the intestines should not deter the surgeon from trying to save his patient.

Prof. Trendelenburg (of Bonn) reports a case in which perforation had taken place already, but after a free incision and drainage, several liters (quarts) of pus were discharged, and the patient got well without peritonitis setting in. No irrigations were made. This shows that by timely interference even septic peritonitis may be prevented.

Prof. Kraske (of Freiburg), in speaking of

Artificial Respiration and Circulation,

reports a case of a boy five years old, who was brought into his clinic suffering from diphtheritic croup. He had not had a respiratory or cardiac movement for ten minutes. Kraske performed tracheotomy, and then artificial respiration (Sylvester's method); the effect was that the boy showed some color after five minutes, and his lips and cheeks reddened, while the pupils contracted (from the filling of the iris-vessels with blood). But no spontaneous respiratory movement took place. Kraske has experimented on animals, and shown that a modified circulation is established by pressure on the ribs or the diaphragm, even where respiration is at a stand-still. Therefore, in cases of asphyxia, from any cause, the subject should be turned upside down—as advised by Sims—and artificial respiration should be induced. The movements should be made strongly and in such a manner that an assistant presses the diaphragm towards the heart at the same time. Then the congestion of the liver and inferior vena

* Dr. H. B. Sands advanced the same view recently in a discussion on the subject in the N. Y. Surgical Society.

cava is relieved by aspiration and gravity, and the right auricle is emptied into the right ventricle. This aspiration is rendered still more effective on the circulation by having the nose and mouth closed by an assistant during, every tenth movement.

Upon the theory now advanced by some, that death by chloroform is caused by the development of bubbles of gas in the heart itself, this squeezing-out of the heart would be just the right thing to give relief.

Dr. Heusner (of Barmen) has made the same observations in a case of sudden death from a cerebral tumor. The pulse could be felt again after artificial respiration had been begun. This was kept up for four hours; but as soon as it was abandoned the color changed and the pulse ceased beating. The same took place in a girl 22 years old, who became asphyxiated after the inhalation of 20 gr. (f3.v.) of chloroform. Life was prolonged for five hours (with an occasional spontaneous respiratory movement), but cyanosis always set in as soon as the artificial movements were discontinued. Heusner thinks that a position with the head hanging down is safest while administering chloroform.

Prof. Langenbuch (of Berlin) has opened the thorax and pericardium in such a case, and squeezed the heart with his hand. Change of color took place, but life remained extinct.

Prof. Rosenbach (of Göttingen) has succeeded in isolating a specific fungus as the cause of

Erysipaloid, or Erysipelas Chronicum (Grocer's Hand).

He has proved by auto-inoculation on his arm that it is the real cause of this troublesome and persistent diseased condition.

Prof. Helferich (of Greifswalde) presents a patient suffering with

Myositis Ossificans.

The disease began in 1875, when the patient was 12 years old. Helferich has had him under observation since 1879, when the disease became stationary. There are large antler-like ossifications on the back, over the *latissimus dorsi* and the *erect* or *spinæ* muscles; others are over the *biceps*, the *triceps*, and the *masseter* muscles. He further showed the peculiar deformities almost always associated with the disease: ankylosis of the two phalanges of both thumbs, and shortening of the big toes by distortion or entire absence of their first phalanx.

Prof. von Volkmann (of Halle) coincides with Helferich's view that *myositis ossificans* is a disease of abnormal growth because it is found only during the period of development; and that it is not an inflammatory affection. It is not allied to muscular rheumatism, as was held formerly. The detection of a real cartilaginous epiphysis with a border of ossification by Volkmann while operating on such a patient, leads him to think it might be analogous to Virchow's *exostosis cartilagena.*

Helferich then describes a case of

Malignant Tumor of the Kidney, Causing Metastatic Tumors in Various Parts.

The autopsy in the case of a man 62 years old, who had a large tumor in the region of the left shoulder and clavicle, and a smaller one in the neck, showed a sarcoma in one kidney and metastasis in the liver. The other tumors were also of a sarcomatous nature. The body of the fifth cervical vertebra was fractured, which accounted for paralytic symptoms observed during life. Operation had been refused on this account.

Prof. von Bergmann (of Berlin) reported a similar case: A man with a large pulsating tumor of the tibia was sent to his clinic for operation. A large tumor of one kidney was detected on examination, and operation refused. Soon metastatic processes developed in other parts of the body. The kidney tumor was considered the primary lesion.

Prof. Israel (of Berlin) reported a case in which a tumor of the renal capsules had caused metastatic processes. A patient was sent to him in whom a *caries sicca* of the humerus was suspected. But Israel found several tumors about and above the shoulder. The autopsy revealed carcinomatous degeneration of both renal capsules, and innumerable metastases in the lungs, liver, and other organs.

(*To be continued*).

Application for Keeping the Hands Soft and Smooth.

Prof. Valenta recommends a simple procedure. The hands, after washing and drying thoroughly, are well anointed with *unguentum emmoliens*—cold cream; a small quantity of *spiritus saponatus* is poured in the hollow of one hand, and this rubbed vigorously until a lather is produced. The fatty lather is merely rubbed off.

This method has been employed in the professor's clinic for twenty years, and in consequence his hands are much admired for their smoothness and natural color.—*National Druggist.*

EDITORIAL DEPARTMENT.

PERISCOPE.

Apoplectic Symptoms Relieved by Stretching the Sphincter Ani.

In the *Lancet*, May 21, 1887, Mr. John W. Teale reports an interesting case in which symptoms somewhat like those of apoplexy seemed to be caused by obstinate contispation, and were relieved by stretching the sphincter ani, and so unloading the bowels.

The patient was a lady, 64 years old, who looked very ill, and was in a highly nervous state. She had a waxy, yellow complexion, and looked wan, anxious, and careworn. She said she had suffered much from constipation, had had severe attacks of what she called "angina pectoris," and that she lived in perpetual dread of having accumulations in the bowels, from which she had suffered. Treatment by mild alteratives, stomachics, and aperients proved a complete failure. More severe remedies produced vomiting. After a few days of fruitless efforts to relieve the bowels, Mr. Teale examined per anum, and found a very tight sphincter. With considerable difficulty he passed a finger through it into the rectum, which he found distended and loaded with hardened feces—the cause, no doubt, of the straining, discomfort, and sense of weight. Operation seemed inadmissible. Careful and repeated castor oil enemata were given for some days, to gradually unload the lower bowel and break down the accumulated mass. Several times a considerable quantity of old feces was removed, and often the patient had some gleams of returning health and spirits. One day she took two injections, which were ineffectual, in spite of considerable straining. About 10 p. m. she became very restless and excited, and almost beside herself, wandering from room to room, scarcely recognizing those about her, constantly making attempts to relieve the bowels. About 6 a. m. the next day, whilst on the night-stool, her maid noticed her face twitching, and these twitchings increased until they amounted to violent convulsions. She soon had slight but well-marked symptoms of paralysis of the left side of the face, which gradually became more decided in character, extending to the left arm and leg. The pupils were regular, somewhat contracted, slightly sensitive to light. There was no stertor, but insensibility was complete. Every few minutes there was a convulsive attack, commencing with twitchings of the left side of the face, extending gradually to the left arm and leg, and then becoming general over both sides of the body, and gradually relaxing without pursuing any definite order. A copious enema of soap and water and olive oil was given, and was retained for four hours. The convulsive attacks continued every few minutes, were more frequent and violent, and insensibility complete. On examining *per anum*, hardened feces could be felt floating about in the enema fluid, though, even in her insensible condition, the sphincter was so tight that the finger could only be passed through it with difficulty, nor would it allow a drop of fluid to escape.

Mr. Teale now stretched the sphincter freely. Immediately the enema fluid poured out, followed by a copious mass of offensive feces of various stages of antiquity. The convulsions continued as before. Forty grains of bromide were injected twice, and were retained. The convulsive attacks ceased after the second dose of bromide, and there were slight natural movements of the right side, but none of the left. In the evening there was another extensive action of the bowels; patient still unconscious.

July 9th. The next day there was no return of convulsions; the bowels moved freely. The patient moved her left leg slightly. After this she slowly recovered. For some days she misplaced names and words. The right side of the body soon regained power, the left more slowly, and remained for some time weaker than the right. In about three weeks she returned home.

Mr. Teale thinks the operation lengthened the patient's life for nearly a year, and also relieved her from suffering. The fact that prolonged constipation from any cause is an important factor in causing apoplexy, when the coats of the arteries are degenerated, has long been recognized—an argument, no doubt, for the early and effectual surgical relief of affections of the rectum, where they are found to exist.

The Treatment of Colds.

This is an old subject, but worthy of attention. Dr. J. H. Whelan, of London, has found the large dose of an opiate in the early stages, as extolled by Sir Thomas Watson

and Dr. George Johnson, very unpleasant and of but little use. Trying to avert an attack by a large dose of potassium iodide failed in his hands. The bromides were useless in all stages. Antiseptic inhalations and spraying afforded temporary relief from distressing symptoms, but failed to cure. Belladonna, quinine, and arsenic were found useful when given separately—not so much in large as in small doses. When combined he believed them to be nearly specific—prophylactically and therapeutically. The formula he invariably uses is as follows:

℞.	Quininæ sulphatis,	gr. xviij.
	Liquoris arsenicalis, (Fowler's Sol.),	♏xiij.
	Liquoris atropinæ (gr. iv. to water ℥j),	♏j.
	Extracti gentianæ,	gr. xx.
	Pulveris gummi acaciæ, xxx q. s. ut fiant pilulæ,	xij.

Sig.—One every three, four, or six hours, according to circumstances.

If these pills be commenced in the early stage of a common cold, *i. e.*, when the affection is as yet confined to the nose and pharynx, the affection will be nipped in the bud. At starting one pill should be taken every three or four, and later one every six hours. If a catarrhal subject has a box of these pills always at hand, he has, Dr. Whelan believes, a weapon wherewith to meet and defeat his enemy. The longest time he has seen a cold last, whilst the patient was fairly taking these pills, was three days. How the remedy acts he does not know, except it be as a powerful nervine and general tonic, bracing the patient's tissues up to resist the attacks of the exciting cause of the affection.—*The Practitioner.*

Diuretic Action of Calomel.

Following up the work of Jendrassik upon the diuretic action of calomel, Dr. Paul Terray, of the Korànyi'schen clinic in Budapest, reports the results of his experiments upon nine patients afflicted with valvular disease of the heart, with nephritis or hepatitis. From the third to the seventh day of the exhibition of the drug, the increased diuresis began, and reached its acme rapidly thereafter —on an average about the second day, sometimes as late as the tenth. In seven cases the urine was ten-fold, confirmed during fourteen trials. The greatest excretion in 24 hours was 6300 cubic centimetres, the smallest 1600, the average 3000. The continuance of the polyuria lasted from three to ten days, falling gradually to the normal. If the calomel were continued when polyuria began, it had no effect, as a rule, upon the subsequent course of the diuresis. Dropsy of the lower extremities, sometimes of the upper, was always noted, exactly in proportion to the polyuria. Quantity of calomel and of the resulting polyuria were not always proportional. Specific gravity of the urine and the quantity of the contained albumen were in inverse ratio to the amount of urine. There was always an increase of chlorides. Diarrhœa and stomatitis usually accompanied the increased amount of urine. The heart's action was always directly influenced. The regularity and fullness of the pulse were in proportion to the amount of dropsy. The author concludes that calomel is a trustworthy diuretic, and that it is indicated in cases of uncompensated valvular lesions with dropsy of the lower extremities, producing relief and improvement in a relatively short time.—*Allgemeine Medicinische Central-Zeitung, April* 13, 1887.

On Notches in the Upper Central Incisor Teeth which Resemble those of Syphilis.

There is a state of notching of the upper incisor teeth, which affects the two central ones of the permanent set, and produces a condition very deceptively like that of syphilis. The notches are central, and very conspicuous. A chief point of difference from the syphilitic tooth is that the tooth is usually wide instead of narrow at its free edge. Syphilitic teeth almost always show narrowing, like a screw-driver, as well as notching. Another point of difference is that the teeth, when looked at carefully, are seen to be craggy and very hard, not worn as the syphilitic tooth. In a very marked example of the pseudo-syphilitic notching, the father of the patient told me that the condition was hereditary, and the youth's mother had teeth of the same kind. In this instance, there was no history of fits in infancy or of the use of mercury or teething powders. Nor, indeed, were the conditions those of stomatitis, or mercurial teeth. The defects occurred in pairs of teeth, and did not damage the whole row. Nor were the first permanent molars—the test teeth of the mercurial set—involved. I have in several other examples of craggy teeth been assured that the peculiarity was in the family. I feel certain, therefore, that we must admit inheritance as an occasional explanation of peculiarities in the form of the teeth. I was once shown, in one of the Paris hospitals, a pair of teeth such as those which I have above described, and great surprise was ex-

pressed that I could not admit that they were characteristically syphilitic.—*Jonathan Hutchinson, in the British Medical Journal.*

Creasote Successful in Phthisis.

Prof. Sommerbrodt, of Breslau, in the *Allgemeine Med. Central-Zeitung*, April 20, 1887, strongly recommends the use of creasote in the treatment of consumption. Measures of a hygienic character are not to be neglected; but Sommerbrodt has rarely had to use any other medicament than creasote, and only for urgent indications. He finds that, at the beginning of the treatment, patients sometimes complain of disagreeable eructations after taking the medicine. But they soon get over this; and come to miss the drug when they omit the dose. The treatment must be continued for months, although it may have to be omitted for a short time occasionally. In women Sommerbrodt has found that prolonged administration of creasote sometimes causes a too free menstrual flow. For this reason he has been in the habit of discontinuing its use at the times of menstruation.

Creasote has also appeared to be a valuable remedy in the treatment of enlarged lymphatic glands, in scrofulosis. In the practice of Sommerbrodt creasote has diminished the cough in phthisis, not only when there was free secretion and expectoration, but also when there was very little. This has enabled him to dispense almost entirely with the use of morphia. At the same time he has seen the fever abate, the appetite improve, and the physical signs of consolidation disappear. He gives the creasote in capsules, each containing about ¾ gr., of which he orders one to be taken three times a day, and sometimes gives as many as three capsules thrice a day.

Analgesic Effects of Antipyrin.

In the French Academy of Sciences, session of April 18, 1887, M. Germain Sée read a paper upon the action of antipyrin upon pain. "The hypothermic property of this drug is to-day of only a secondary interest in comparison with the remarkable effects it produces upon pain. In the paroxysms of acute or chronic gout or in the attacks of rheumatism, the suffering quickly disappears under the administration of four to six grains of antipyrin given every day for a week. But it is particularly in nervous affections that antipyrin has its greatest effect. Facial neuralgias and migraine yield quickly to it. The fulminant pains of beginning locomotor ataxia are calmed by antipyrin as well as by acetanilide, and the former has the advantage of being more easily used and less dangerous. The distressing pangs of some cardiac, aortic, and arterial diseases are quieted by four to six grains. This valuable agent should always be given in doses of one grain in half a glass of cold water at intervals of one to three hours. The most serious inconvenience met with in its use consists in the appearance of an eruption similar to that of scarlatina, but this soon disappears. The experiments upon animals made by M. Gley prove that antipyrin produces a real analgesia of the limb when injected subcutaneously; it seems to act upon the nerve-endings. However this may be, antipyrin is one of the most efficacious and harmless remedies for pain."—*Le Progrès Médical, April* 30, 1887.

Tuberculosis of the Tongue.

Feurer discusses the tuberous form of tuberculosis of the tongue, and calls attention to the difficulty of the differential diagnosis that may exist between this and carcinoma, especially in old people. He thought he had extirpated a carcinoma in an individual 72 years of age, and was surprised to find that the trouble was tuberculosis. (V. Volkmann reports that he had also twice made this diagnostic error.) The tongue shows fatty ulcers with infiltrations penetrating deeply into its substance, and with firm and more or less sharply limited borders. Tuberculosis is characterized by absence of radiating pains and by the character of the glands, which are never so large as in carcinoma. In tuberculosis there are of course also other localities of the body affected. But if these diagnostic points are absent, only an incision can make the case clear. In the endeavor to prove the existence of the tubercle bacillus, a single negative result is not to be considered decisive. The therapeutic proceeding is alike in both cases, since in tuberculosis the most complete removal of the affected part by the knife is also necessary.—*Allgemine Medicinische Central-Zeitung, April* 9, 1887.

How to have Good Milk for Infants.

Simoris, a Netherland physician, recommends cleansing the nursing apparatus of artificially-fed infants by soaking it in lukewarm water, boiling the whole apparatus for a quarter of an hour, and then allowing it to cool off gradually. He says that the rubber tubing stands this process very well,

so that about a yard of it will last for a year. By this means he has almost always avoided causing dyspepsia. He calls attention to the careless practice of some mothers or nurses who add fresh milk to what is left over from a previous feeding. The attempt to sterilize milk by boiling it, Simoris thinks rather harmful than beneficial, since it makes the coagula of casein in cow's milk much harder to digest. Fresh milk from healthy cows is not dangerous, and a good condensed milk comes next to this in value. —*Allegemeine Med. Central-Zeitung, April* 20, 1887.

Anthracosis of Both Petrous Bones.

Dr. Friedrich Betz, of Heilbronn, reports in *Memorabilien,* May 10, 1887, a case in which he discovered a condition of the petrous portion of both temporal bones, which he considers anthracosis. The subject had been a miner who was killed by accident. At the autopsy his lungs were found to be very deeply stained with coal-dust; and a similar condition was found in both petrous bones. There was no evidence of disease in these bones, and Dr. Betz thinks there can be no question of the condition being one of melanosis. The only way to account for the black pigment which was seen just under the vitreous table of the bones was on the supposition that it was coal-pigment, which had found access to the petrous bones through the middle ear.

This is very far from a satisfactory way to account for the remarkable operation of Dr. Betz. As to the observation itself we make no question, in view of the reputation of man who made it.

Antipyrin in Otalgia Nervosa.

For pure otalgia nervosa Gompertz has given antipyrin in doses of fifteen to twenty-three grains. In two out of the seven cases so treated the result was extremely brilliant. In one case of bilateral otalgia that had persisted for more than a month, permanent cure was effected with fifteen grains. This result was produced in a second case with thirty grains. In two instances there was only a temporary relief, and the results in three cases were not observed.—*Allgemeine Medicinische Central-Zeitung, May* 14, 1887.

Pruning Shears for Use in Autopsies.

Dr. T. E. Quimby, of Fayetteville, N. Y., writes to the *N. Y. Medical Record:*

"I have been using at autopsies the pruning shears No. 52,' to be obtained at hardware stores at a cost of fifty cen They sever cartilage or ribs with rapidi and ease, being vastly superior, I find, to the cartilage-knife. It is an excellent instrument as regards size, weight, strength, an d finish, keeping sharp a long time."

Turpentine for Malignant Tumors.

Prof. Vingt, of Barcelona, in the *Revist a di Cirencias Medicas,* claims to have secured the partial or total disappearance of carcinomata by injecting into them with a hypodermic syringe about 30m of a mixture o f one part turpentine and one or two parts o f alcohol.

Reviews and Book Notices.

BOOK NOTICES.

The Cremation of the Dead considered from an Æsthetic, Sanitary, Religious, Historical, Medico-Legal, and Economical Standpoint. By Hugo Erichsen, M. D., with an introductory note by Sir T. Spencer Wells, Bart., F. R. S., pp. 275, Detroit: D. O. Haynes & Co., 1887. Price $2.00.

This little book gives a precise account o the origin and development of cremation; of the evils of burial; of the sanitary aspect of incineration; attempts to answer all the objections which are brought against this custom, and considers the question from a religious point of view. The advantages of cremation are so skillfully presented here as to produce the impression that no strong argument can be advanced against its introduction except that of sentiment. But the feelings have a great influence in shaping opinions and customs, are often as legitimate, and often have as good a right to be respected, as views which are purely intellectual. They guide us sometimes when reason fails; they may also dominate us when our reason is clearly in the right. There can be no question, however, that on the subject of cremation the position of sentiment is erroneous, and will eventually coincide with or be compelled to submit to the inevitable dictates of reason. Such a day, we conceive, is not far distant, and any misgivings or objections which may arise will speedily vanish after a thorough perusal of this book. T. J. M

Oration Delivered by Request before the Medical and Surgical Society of Baltimore, Md., commemorative of Dr. Augustus Frederick Erich. By Thomas B. Evans, M. D.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 *reprints will be furnished, in place of payment, if a request is sent with the manuscript. Contributors should* ALWAYS *state which form of remuneration they desire: reprints, extra copies of the* REPORTER, *or cash.*

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER will be published in each number. The regular edition for this week is 4,800 copies.

THE PROGRESS OF ORTHOPŒDY.

The announcement which has lately been made of the organization of the "American Orthopœdic Society," furnishes an appropriate opportunity for some remarks on the claims of orthopœdic surgery as a specialty, its progress and status. For many years a few eminent men in the profession have devoted themselves to the study and rectification of deformities by mechanical means, and prominently among these may be mentioned Davis, Bauer, Taylor, Prince, and Sayre; yet they were generally regarded as having had large experience in joint diseases and deformities in the course of a surgical practice, rather than as specialists in the strict sense of the term. Thus, with exceedingly limited exceptions, this branch of professional work, twenty years ago, was either in the hands of charlatans, who knew nothing of the nature of the diseases they were called upon to treat, or the instrument-makers, to whom, as a rule, these cases were referred by the profession for apparatus, which they suggested, made, and applied, without the adequate knowledge to scientifically understand the requirements and indications for treatment in the cases that fell into their hands.

Indeed, the whole subject of orthopœdic surgery was supposed to consist in a knowledge of club-foot, possibly from a mistaken idea of the origin of the term, yet Audrey devised it to include the whole subject of the rectification of deformities, whether congenital or acquired.

The first step toward the recognition of orthopœdy in this country as a special branch of surgery was the establishment of a chair for the separate consideration of the subject by the Bellevue Hospital Medical College, early in its career; and Prof. Sayre, then as now, taught this subject, including diseases of the joints and spine with the more ordinary deformities. At present American orthopœdics embraces a large range of subjects, and the advance made in the mechanical treatment of joint and spinal diseases by distinctly American methods marks an epoch in the history of surgery.

Another impetus to the study of this subject was given by the establishment of special hospitals and dispensaries for the treatment of deformities and kindred troubles. Foremost amongst these may be mentioned the New York Orthopœdic Dispensary and Hospital, where for many years these diseases have been systematically treated, besides furnishing opportunities for professional studies by lectures, clinics, etc. As a direct result of the methods taught in this institution, a similar dispensary has been established at the Hospital of the University of Pennsylvania, where, during the past five years, many cases of deformities, joint and spinal diseases have received treatment, while clinical instruction was afforded to the students.

From these centres, so to speak, many young men have been sent forth apostles of the specialty, and now in all parts of the United States are found those especially devoted to its advancement and interests; the contributions to medical literature having been in this department fully as progressive and important as in other well recognized specialties.

It is then with pleasure that we notice the organization of a national society, where ideas may be fully interchanged, and where anything tending to the relief of these chronic, painful, and in many instances neglected diseases, may be brought forward and given the benefit of the experience of experts from all parts of the country.

A MISSING LINK.

The *Concours Médical*, of April 23, 1887, publishes gravely the following interesting item:

"M. Janssen communicates, for M. De Lesseps, the following fact in regard to hydrophobia, which is of peculiar interest on account of its clearness. M. Charles De Lesseps had in his stable two dogs. One of these dogs became rabid, and bit the groom, who was treated at the Pasteur Institute, and is to-day perfectly well. The dog which bit him simply licked—probably on an excoriation of the skin—the other dog, which in its turn bit a second servant. The latter paid no attention to his bite, and he has just died with all the symptoms of convulsive hydrophobia."

This item sounds as if it were a strong confirmation of the value of Pasteur's method of treating persons supposed to have been bitten by mad dogs. But, there is an important link missing. What was the fate of the dog which was licked? Is it alive and well, like so many of the dogs which furnished patients for Pasteur?

REPORT FROM THE SIXTEENTH CONGRESS OF GERMAN SURGEONS.

In this number of the REPORTER we present our readers with part of an abstract of the proceedings of the last Congress of German Surgeons. This has been furnished us by a special correspondent, and contains very valuable opinions from some of the most eminent surgeons in the world.

We call attention to this report not only because of its scientific worth, but also because it is one of the first fruits of arrangements by which we shall give to our readers very promptly the best of what is going on in every part of the world, not only in surgery, but also in medicine.

AMERICAN MEDICAL ASSOCIATION.

Thirty-eighth annual session, held in Chicago, June 7th, 8th, 9th and 10th.

First Day—June 7th.—General Session.

(*Continued from page* 759.)

SECTION OF OBSTETRICS.

Dr. Wathen, of Louisville, read an interesting report of a case of

Rupture of the Uterus,

the rupture extending on the left side from the os externum to the middle of the fundus, splitting the uterus into halves. The liquor amnii was discharged a week before the uterus ruptured. The doctor suggested that the uterine tissues were in a condition of fatty degeneration, or that there was some form of inflammation, for the contractions were too insignificant to otherwise have ruptured it. He advised laparotomy in all cases of complete rupture, and expressed no little surprise that there are some well-known medical writers, and many good practitioners and surgeons, who refuse to acknowledge that abdominal section is the best and safest treatment in rupture of the uterus. The operation adds but few dangers, and removes many. In all cases the rent should be well sutured, or the uterus removed by Porro's operation. Sänger reports sixteen operations for Cæsarian section, with but one death, saving all the children. These operations were performed in the Maternity Hospital of Leipzig, and the Dresden Maternity Hospital, by Sänger, Aberman, Donat, Leopold, and Cohn. Of course he did not expect such results in general practice, but timely cases by expert operators would result in a success of over 75 per cent. In conclusion, he suggested the substitution of some form of abdominal section for craniotomy where the child is living.

PRACTICE OF MEDICINE.

Afternoon Session.

This section was called to order by the President, Dr. J. S. Lynch, of Baltimore, at 3 p. m.

Dr. C. N. Cooper, of Cleveland, Tenn., read a paper on

Glanders in the Human Subject, with a Case.

This is essentially an equine disease; found among horses, asses and mules the world over. The names equinia and farcy are also applied to this malady. Its prevalence in any country is said to increase from 50 to 100 per cent. during and after a war. Some agree that every case is to be traced to some other, as in measles or small-pox in the case. Others claim that under some circumstances it originates *de novo*. All agree, however, that there is a glanders bacillus, but do not agree as to whether it is the essential cause. A very large majority agree that this disease never originates in the human subject; but I believe that its virus is a fixed poison, like that of vaccinia or syphilis, and cannot be conveyed from one person to another except by some form of inoculation. The first case reported was by Lorin, a Frenchman, in 1812. The next was by Muscroft, of Edinburgh, in 1821. Copeland, of London, also reported

a case about the same time. The period of incubation occupies from three to five days. The attack is ushered in by more or less pain, like that of rheumatism, yet without local inflammation, and an indescribable feeling of languor. The temperature soon becomes high, the pulse quick, weak, and unsteady ; the tongue is heavily coated and soon becomes dry and brown. There is constipation and scanty urine. The teeth and lips rarely take on sordes. Nodules form about the face and body, and often break down, with bullæ. Deep abscesses form, involving both the cellular and muscular tissues, which are painful and mature very slowly, discharging, when opened, a thin, dirty, sanious pus.

Dr. Henry J. Reynolds, of Chicago, read a paper on

A New Method of Producing Local Anæsthesia of the Skin.

Knowing that solutions of cocaine are not readily absorbed by the skin, and therefore produce no anæsthetic effect, Dr. Wagner, of Vienna, about a year ago made experiments, the results of which he afterwards presented to the Society of Physicians or Vienna in the form of a paper on that subject, with a view to obtaining a more successful method of producing anæsthesia of the skin with this drug. He found that by saturating the positive electrode of a battery with a solution of cocaine, applying it to the skin, and then applying the negative electrode a short distance from the positive, with a moderate current, successful anæsthesia could be produced.

After considerable experimentation, I now use an eighteen cell McIntosh battery, but I think in some cases even a stronger current is necessary. For reasons not necessary to discuss at present, the Faradic current will not answer. The strength of the current must vary with the sensitiveness of the part, the size of the electrode, etc. It is always necessary to use the strongest current that can be borne, which may vary all the way from four to five cells to twenty-four, but for which no rule can be laid down, the only guide being the feelings of the patient and the experience and discretion of the physician. Where the skin is very dense, and the part not sensitive to electricity, the electrode must be large, owing to the greater surface necessary to be acted upon. This renders the current more diffused, and hence in a sense not so strong; the current must therefore be very strong, requiring perhaps eighteen cells. The sponge on the electrode used for the solution should be of the finest and softest quality. When a strong current is used the irritation at the negative pole may be avoided by using a larger electrode.

In my experience the cocaine should be used weaker than a five per cent. solution. It may vary, however, owing to circumstances, from two to a twenty per cent. strength. Where the skin is thin, and the part will tolerate a strong current, a two to five per cent. solution will answer. On the other hand, if the part be so sensitive that only a weak current can be employed, as in portions of the face, the solution to be effectual must not be less than ten per cent.

Saturate the positive electrode with the solution, and place it directly upon the part to be anæsthetized. Place the negative electrode, well saturated with water, on some point near by. A more remote point, as the hand on the opposite side, for instance, will answer, but it will take longer time and a stronger solution to get the effect than when placed near by. In working about the face, I think it is better to hold the negative electrode in the hand than to apply it to the face near the positive, as in this way a stronger current will be better tolerated.

It is well for the operator to familiarize himself with the method by experiments upon his own person. The electrodes should be kept firmly pressed to the skin, the positive being now and then moistened with more solution, as required, and the negative with more water. If the negative produce much irritation, it may be occasionally shifted to another place.

The time required to produce anæsthesia depends of course upon the location, the strength of the solution, the strength of the current, etc. In the skin of the flexor surface of the forearm, if the negative pole be applied near by, a five per cent. solution with about ten cells, will produce profound anæsthesia in five minutes. If the negative pole be placed in the hand of the opposite side, about double that length of time will be required. Wherever the skin is dense, a longer time, stronger solution, and stronger current are necessary. In any case the current should be allowed to run as described till anæsthesia is produced, as ascertained by gently pricking now and then with some sharp instrument.

The duration of anæsthesia varies more or less also with the circumstances; as a rule, however, the effect is rather transitory, lasting perhaps from five to fifteen minutes.

In the operation for the removal of super-

fluous hairs from the face by electrolysis, I have frequently used it. In this operation, inasmuch as the tissues still conduct the current, an ordinary electrical sensation is experienced by the patient, but the sharp, stinging, burning pain at the site of the needle, sometimes so acutely felt, is, when the method is judiciously employed, entirely done away with. In the removal of small warts, nævi, etc., from the face by the knife, it is even more satisfactory. One obstacle in the way of its successful employment in certain portions of the face is the extreme sensitiveness of the part, owing to which condition a sufficiently strong current to induce the necessary absorption of the drug cannot always be tolerated. In a case of felon of the palm, I made a very careful effort with a ten per cent. solution and sixteen cells to produce anæsthesia, previous to lancing. In this case the method, as I employed it, was not a success. Failure in this case was explicable by the following reasons: First, the skin was very thick and callous; second, owing to the extreme soreness sufficient pressure with the electrode could not be made to get the full benefit of the current; third, I think under the circumstances the current was not nearly so strong as it should have been. In dental surgery I think the method can also be used to advantage. I applied it in one case for Dr. W. H. Gale, of this city; the patient was a lady for whom two teeth were extracted. It is, of course, impossible to determine in such a case exactly how much benefit is derived from the procedure, but as nearly as could be ascertained, the pain in this case from the extraction was comparatively insignificant. Ten cells were used with a ten per cent. solution.

SECTION ON SURGERY AND ANATOMY.

In this section Dr. W. C. Wile, of Philadelphia, read a paper on

Scirrhus of the Mammæ, Illustrated by Twenty-five Cases.

In operating upon the mamma for cancer, the same broad principles of surgery must be applied that are applicable to surgical interference upon any other part of the human economy. It will be of inestimable value to an operator when he has finally mastered the maxim that the principle never changes whatever the site of the disease may be. During the last few years he had practiced antisepsis in operating upon these cases, as he did in all his other surgical work, and he was sure the healing of the wound was so greatly accelerated that he shall never attempt the same operation without taking this precaution.

A paper on

Retroflexed Splints for Fracture of the Forearm,

was read by Dr. W. D. Kearns, of Pittsburgh.

No bone of the human skeleton, except perhaps the clavicle, is so frequently the seat of fracture as the radius, and no fracture has, perhaps, received greater practical study than that of the lower end of the radius, known as "Colles's fracture." Reference was made to the ingenious instrument devised by Dr. Gordon, of Belfast, after long and continued anatomical study of Colles's fracture. Whether the fracture of the radius be transverse, oblique, more or less longitudinal, or more or less comminuted, the conditions governing the form of retaining splints are, after complete reduction, alike exacting, and best maintained by retroflexed splints, which seem greatly effective in preventing a formidable impairment of the functions of flexion, extension, pronation, and supination. The essential principles maintained in the treatment of not only Colles's fracture, but in that of all fractures of the radius and ulna, may be generalized as consisting of careful and complete reduction; in the maintenance of complete relaxation of the muscular tendons of the arm, forearm, and hand, of the fasciæ and ligaments, of both superficial and deep flexors of the anterior brachial region and of the superficial and deep extensors of the radial region to their tendinous insertions, even to the short and seemingly unimportant muscles and fasciæ of the palmar surface of the thumb. The early free use of the thumb adds greatly to the early use of the hand.

Dr. Frederick F. Schaefer, of Chicago, exhibited a young woman of about twenty-two years of age with

Complete Loss of Scalp, including the Greater Portion of the Eyelids and one Ear; Treatment by Skin Grafts,

and made the following extemporaneous remarks:

The case I show to you came under my notice in July last. The scalp was torn off from the margin of the eye-lids near the eyelashes, over the nasal bones, from there around the sides of the head, below the left ear, taking off this (left) ear, extending back and around the neck an inch and a half below the superior curved line of the occipital bone. On the right side of the head the tear extended through the lower third of the ear,

allowing the ear to swing by a narrow neck of skin one-eighth of an inch wide. The entire periosteum was torn off in three places, over elliptical surfaces each about three inches in length by two and a half inches in width. The nasal bones were crushed, exposing the nasal meatuses; the zygomatic processes were also broken; all the muscular tissue was torn from the head, excepting a few fibres of temporal muscle on the right side. The neck flap dropped away from the surface of the trapezius muscle exposing this muscle almost to the shoulder blades. Every artery of the scalp going to the head was torn off. The posterior auricular, occipital and temporal arteries had to be tied. The supra-orbital nerve was broken off at the supra-orbital foramen. The dimensions of the wound were: greatest diameter antero-posterior 16½ inches, and the greatest transverse diameter (over the ears) 13½ inches. The scalp was put back soon after the injury occurred, and the wound was trimmed and stitched. The right ear was also stitched on, and has grown fast again. The patient had to remain in the sitting posture for two months, and at the end of six weeks skin-grafting was commenced. Up to the present time 4,500 grafts, both autoplastic and heteroplastic, have been applied, the autoplastic grafts consisting of a little more than one-third. The entire number of grafts was taken from herself, her brothers and her sisters. Average size of grafts as small as a pea. The dermis, as well as the epidermis, was used. During the first three months only epidermic grafts were used. These grew very rapidly, but the skin was immovable, and it had scarcely formed when it began to ulcerate, and pieces of skin eight inches in length by 2½ inches in width were lost. I then concluded that the dermis would make a more reliable skin, and used it from that time. At the present time the head is about eight-ninths covered by a fine skin, and it may be regarded as a good skin. The older portion of the scalp first grafted can be pinched up with the fingers to the extent of about three inches on the forehead; the pores of the skin are plainly visible; the patient can close her eyelids, although they are somewhat drawn. The portion of the cranium which remains uncovered is behind the middle of the head, and consists of a few spots, the combined measurement of which would form one-ninth of the whole scalp, eight-ninths having therefore been reproduced. The entire new skin may be moved by gentle manipulation with the fingers.

This case is of unusual interest on account of the great area of the wound, and the satisfactory results of the treatment up to the present time. I was forced to re-graft some portions several times, and became almost entirely discouraged with the loss of large surfaces of skin. I found also that the autoplastic grafts were more certain to grow than the heteroplastic. On an average about 85 per cent. of her own grafts took, of the others an average of about 40 per cent. It may be necessary to add that I have had a good case to work on; the patient is very plucky and has an unusually good constitution. Several pieces of bone as large as a ten-cent piece were removed from the outer table, where the periosteum was uncovered. The grafts were placed around the circumference of the wound in double rows, from 20 to 100 at a sitting. When the circle of grafts was complete, I would wait until blood-vessels were developed in this circle before grafting another, which would usually take about two weeks. The grafts were placed directly in contact with the surfaces of the granulations. Dr. J. D. Skeer, of this city, assisted me during the first month the case was in my hands, and helped me to sew up the scalp.

June 8th—Second Day—General Session.

Dr. J. S. Lynch, of Baltimore, Chairman of the Section of Practice of Medicine, delivered his address entitled

Consumption and Fevers.

Unquestionably the means of safely reducing and keeping down morbidly high temperatures constitute the most powerful weapons we possess in combating a large majority of the diseases to which mankind is heir. Ninety cases in a hundred of pulmonary consumption die from asthenia long before the destructive processes going on in the lungs have deprived the patient of a sufficient amount of his respiratory apparatus.

Dr. Lynch then referred to antipyrine, the agent discovered by Knorr, of Erlangen, Germany. Early in November, 1884, he began its use in all diseases attended with fever, and his own estimate of its value may be inferred from the fact that since that date he has not lost a single case of enteric fever, scarlatina, or measles, and only one of croupous pneumonia—seen too late; and that the duration of cases of phthisis seems to be very nearly doubled. In acute inflammatory rheumatism it seems to be scarcely less efficient than sodium salicylate. The dose should be about fifteen grains, repeated every hour until three doses have been taken, and afterward every three or four hours. It is

very soluble in water, has a slightly pungent and bitter taste, and rarely excites nausea. If it should do so, it should be given in lime water, or combined with other alkalies. He strongly deprecated Bergeon's treatment of consumption.

SECTION ON DISEASES OF CHILDREN.

Dr. F. E. Waxham, of Chicago, read a paper on

Intubation of the Larynx, with Inferences from 133 Cases.
